Lack of Regulation and Evidence

Sensors and other health care devices remain both understudied and unregulated. Although the FDA is stepping up its effort at monitoring health sensor technology, significant work will be required to establish the safety, validity, and reliability of these devices before they are widely deployed. A further issue is that despite a recent wave of technology

Telegram: @medical_k

www.konkur.in

targeting older adults, the majority of these technologies are developed by technology firms and marketed without sufficient evidence to establish the safety, efficacy, reliability, and validity of these devices to perform the tasks they are designed for. There is a great need for data on how these technologies are used and how effective they may be. Geriatric psychiatrists have a great opportunity to be leaders in the area of establishing parameters for technology use and development in medicine.

55.6i Positive Psychiatry of Aging

Barton W. Palmer, Ph.D., and Dilip V. Jeste, M.D.

There is a growing recognition that medicine should encompass not only the treatment of symptoms but also the promotion of well-being. For geriatric psychiatry, this means greater attention to the promotion of “successful aging” as well as to other aspects of well-being among older adults. The notion that mental health is more than the absence of symptoms or disorders is not new. In 1946 the World Health Organization (WHO) published a definition of *health,* which was not merely the absence of disease or disability, but rather “a state of complete physical, mental, and social well-being.” While seemingly self-obvious, this definition is potentially revolutionary in its implications for the practice of geriatric as well as general psychiatry. Yet, approximately 75 years later, the implications of that revolution have still not become fully weaved into mainstream psychiatry. Contemporary geriatric and general clinical psychiatric practice and training remain primarily restricted to the diagnosis and treatment of mental illnesses, while psychiatric research mainly focuses on elucidating the underlying pathology and ameliorative interventions to treat and prevent relapses of mental illnesses. Within the field of Positive Psychology, founded in the late 1990s by Martin Seligman and colleagues, a growing body of research strongly suggests

Telegram: @medical_k

www.konkur.in

that positive psychosocial factors (PPSFs) such as resilience, optimism, and social engagement are associated with higher levels of subjective well-being as well as lower morbidity and greater longevity. With the founding of positive psychiatry approximately 10 years ago, subsequent psychiatric research has shown the association of PPSFs with better well-being, lower morbidity, and longevity also generalize to those living with serious mental illnesses. Although many key questions still need to be addressed through empirical research, the last decade has finally brought together the empirical foundation for positive psychiatry as a potentially key aspect of 21st-century psychiatry.

DEFINING POSITIVE PSYCHIATRY

Positive psychiatry is the science and practice of psychiatry that seeks to understand and promote well-being through assessment and interventions aimed at enhancing behavioral and mental wellness. As a part of psychiatry, itself rooted in the field of medicine, positive psychiatry is grounded in biology and ultimately seeks to determine the neurobiologic underpinnings of the PPSFs associated with positive outcomes and to use that information to develop more effective biologic and psychosocial preventive, therapeutic, and rehabilitative interventions. As a branch of medicine, an important facet of positive psychiatry that at least partially distinguishes it from the complementary field of positive psychiatry is that it is primarily focused on the promotion of PPSFs and positive outcomes among those with or at high risk for psychiatric or physical illnesses.

HISTORY

In 1906 William James, a physician and psychologist by training, spoke of the need for a new approach to psychology that would study and apply principles underlying the success of the “mind cure.” The concept of *mind cure* referred to the purported healing powers of positive emotions and beliefs. Although in retrospect, the mind-cure movement itself appears an anachronism of questionable validity, James’s emphasis on positive emotions and beliefs illustrates an early effort to include PPSFs during the emergence of psychology as an independent field. Yet these inclinations were largely neglected until the mid-20th century, which

Telegram: @medical_k

www.konkur.in

brought the Humanistic Psychology movement of Abraham Maslow and colleagues. Their focus was on the study and promotion of health and creativity among individuals. But that movement also failed to fully shape psychiatry, as well as mainstream clinical psychology. Instead, positive psychiatry traces its most immediate lineage and debt to the Positive Psychology movement initiated by Martin Seligman and colleagues in the mid to late 1990s. In his 1998 Presidential Address, Seligman spoke of the need for “a reoriented science that emphasizes the understanding and building of the most positive qualities of an individual: optimism, courage, work ethic, future-mindedness, interpersonal skills, capacity for pleasure and insight, and social responsibility.” In the ensuing decades, Positive Psychology has grown and flourished into an international movement, but much of the research has focused on promoting well-being among the psychiatrically and physically healthy, and it has had less impact on the day-to-day practice of clinical psychiatry. This situation began to change over the past decade. In his May 2013 address as President of the American Psychiatric Association, Dilip Jeste commented “I expect that the future role of psychiatry will be much broader than treating psychiatric symptoms. It will seek to enhance the well-being of people with mental or physical illnesses. That is positive psychiatry.” positive psychiatry is allied with and partially overlaps with Positive Psychology in concepts and goals, but also complements in that psychiatrists are first trained as physicians, an applied biologically rooted profession focused on treating diseases and disabilities.

POSITIVE MENTAL HEALTH OUTCOMES

There has been a growing recognition that medicine should encompass not only the treatment of symptoms but also the promotion of well-being. Similarly, the goal of psychiatric interventions should not be just a reduction in psychopathology but also the promotion of positive mental states. Some of the better-known outcomes are summarized below.

Successful Psychosocial Aging

There is no single consensus definition of successful aging. A 2006 review of the empirical literature revealed 29 definitions in 28 published empirical reports. But there were some common themes. Traditional notions of successful aging have emphasized how much one has not

Telegram: @medical_k

www.konkur.in

aged, that is, the relative absence of physical, cognitive, and social disability. However, more recent studies focused on the perspectives of older adults themselves showing that self-perceived successful aging is not dependent on physical health. Large proportions of older adults with chronic physical illnesses, who would not meet objective disability-based criteria of successful aging, perceive themselves as aging successfully. Qualitative studies indicate that older adults consider the ability to adapt to circumstances and a positive attitude toward the future as more important than an absence of physical disease and disability. This distinction between physical disability and self-perceived successful aging may help explain a now well-documented paradox of aging. Specifically, while physical health and functioning, as well as some aspects of cognitive performance, tend to decline with increasing age, subjective well-being begins a steady improvement from youth that continues into old age.

Other Positive Outcomes

Well-Being. Echoing the WHO definition of health, positive psychiatry construes *well-being* as representing the presence of pleasant, positive experiences, and states such as life satisfaction and happiness (hedonic well-being), as well as eudemonic well-being, including a sense of purpose or meaning in life and self-acceptance. The concept of well-being has risen to prominence in recent years in economics, with self-reported well-being considered a measure of national development alongside traditional constructs such as the gross domestic product. Well-being is associated with better health outcomes and with reduced mortality/greater longevity.

Low Perceived Stress. The concept of stress has a complex history; the term may be used to refer to objective pressure or tension or the body's objective response to demands or change. In the context of positive psychiatry, however, the emphasis is on the individual's perception of stress, which appears to be a better predictor of deleterious changes in some biomarkers, such as telomere length, than objective stress. Perceived stress specifically represents the degree to which individuals perceive demands, problems, or challenges as exceeding

Telegram: @medical_k

www.konkur.in

their ability to cope with them. Recurrent unhealthy stress responses lead to cumulative wear and tear.

Post-Traumatic Growth. The link between severe stress and post-traumatic stress disorder (PTSD) is self-evident but not inevitable. Some people who experience significant traumatic events experience a form of personality growth that is referred to as *Post-Traumatic Growth*. It is characterized by an increased appreciation of life, altered priorities, closer interpersonal relationships, a greater sense of personal strength, and/or recognition of new possibilities for one's life. Post-traumatic growth is fostered by the individual's resilience in the face of severe stress–it is not the opposite of PTSD, as they may be copresent within the same individual in response to the same stress or trauma.

Recovery from Serious Mental Illnesses. Contemporary empirical data paint a brighter picture of the course of psychopathology and disability among older people with serious mental illnesses than traditional conceptualizations. For example, relative to their younger counterparts, older adults with schizophrenia tend to have better psychosocial functioning, including better adherence to medications and self-rated mental health, and a lower prevalence of substance abuse and psychotic relapse. There is no consensus definition of recovery (e.g., there are differences of opinion regarding the need for full symptom remission), but there is a general consensus that recovery involves decreased functional dependence and reduction of the impact of the illness on one's life. Elyn Saks has described this capacity as finding "wellness within illness."

Prevention. Prevention is one of the key positive outcomes of positive psychiatry. The focus on prevention has long roots in community psychiatry, where there have been efforts directed at primary, secondary, and tertiary prevention. In recent decades, medicine and psychiatry have experienced a paradigm shift from an almost exclusive focus on treating pathology to promoting health, as well as from caring for individual patients to enhancing the health of communities through preventive measures. Prevention is no less meaningful in the context of geriatric psychiatry. A wealth of empirical data indicate that prevention in later life can be practical and cost-effective.

Telegram: @medical_k

www.konkur.in

Prevention can occur at multiple levels.

a. Primordial: Strategies aimed at altering partially malleable risk factors such as social determinants of mental health like social isolation and discrimination can prevent or at least delay the occurrence of depression.
b. Primary: Treatment or prevention of depression following stroke, myocardial infarction, and/or bypass surgery results in significant reductions in morbidity and mortality.
c. Secondary: Examples include prevention of suicides following successful treatment of suicidal behavior (suicide attempts); prevention of PTSD with counseling after personal or community disasters; and prevention of relapse in schizophrenia, bipolar disorder, or substance abuse with very early detection of prodromal symptoms and signs.
d. Tertiary: Reversing dementia due to vitamin B deficiency with appropriate vitamin supplementation illustrates tertiary prevention.
e. Quaternary: This is exemplified by the prevention of iatrogenic conditions such as antipsychotic-induced tardive dyskinesia, anticholinergic confusion, or delirium.

POSITIVE PSYCHOSOCIAL FACTORS

A key tenet of positive psychiatry is that positive outcomes such as those described above are at least partially mediated by and can be fostered by the enhancement of intrapersonal positive psychosocial traits as well as positive environmental/social factors, together subsumed under the rubric of PPSFs. Most of these factors are valued highly by society, yet until recently, they have been generally neglected in the biomedical sciences as imprecise, amorphous concepts that lack relevance to traditional medicine or neuroscience research. There have been numerous studies in recent years suggesting that the PPSFs are tightly linked to human biology and are associated with positive health outcomes.

POSITIVE PSYCHOSOCIAL CHARACTERISTICS

PPSFs may have as strong(if not stronger) an impact on patient well-being as common health risk factors such as obesity, hypertension, sedentary lifestyle, smoking, and even objective overall health status. The provision of effective interventions to strengthen PPSFs in older

Telegram: @medical_k

www.konkur.in

psychiatric patients could substantially increase the prevalence of recovery in seriously mentally ill older adults. Some of the key intrapersonal constructs (positive psychosocial traits) and positive environmental factors are considered below.

Positive Psychosocial Traits

Resilience. *Resilience* refers to ready recovery from or positive adaptation to illness, depression, or other adversities. Resilience is associated with greater well-being and reduced mortality risk among older adults. People in their 90s who endorse higher levels of resilience have a 43% higher likelihood of living up to 100 years compared to their peers with lower resilience. Among people with medical illnesses, resilience is also associated with better treatment adherence, better self-care behaviors, and improved quality of life. Among physically ill patients, resilience is associated with improved physical health, health-related quality of life, self-care, and treatment and exercise adherence. Resilience is also associated with better emotional health and well-being.

Optimism. The term *optimism* refers to a characteristic of people who tend to expect good outcomes. Optimism is associated with a lower risk of depression and higher overall subjective well-being, lower mortality, as well as less pain, better cardiovascular, oncologic, pregnancy, and other physical health outcomes, and better immune function. The precise mechanisms through which optimism has these effects are not fully clear, but it may partially operate through its effects on health behaviors. Older adults with higher optimism are more likely than less optimistic age-comparable peers to consistently engage in healthy behaviors.

Personal Mastery, Coping Self-Efficacy, and Meaning in Life. *Personal mastery* refers to an individual's expectations of her/his ability to achieve self-desired outcomes. A closely related concept is that of *coping self-efficacy*, that is, the individual's self-perceived ability to perform the requisite coping behaviors needed to overcome life challenges. Individuals high in personal mastery or coping self-efficacy have a belief in control over their life circumstances and future—that is, they have a general sense of control over things that happen to them and have greater confidence they can solve problems in their lives. In

Telegram: @medical_k

www.konkur.in

contrast, *optimism* more broadly denotes a tendency to expect positive outcomes regardless of whether or not one is the agent of those outcomes. In the context of chronic life stress, personal mastery and coping self-efficacy may promote specific, adaptive, goal-oriented behaviors, as well as maintenance of those behaviors, despite ongoing stresses. High levels of personal mastery tend to protect people from the potentially negative effects of stress on general health.

There is also growing evidence showing that *meaning or purpose in life* is associated with better mental and physical health. Developing a purpose leads to greater well-being and productivity.

Wisdom. *Wisdom* is a construct with heuristic value in that it appears across most cultures and contrasts with factual knowledge or even intelligence. Although traditionally, this construct was thought to be the province solely of philosophy and religion, recent successful efforts to develop standardized quantitative measures have also advanced the scientific study of wisdom. Wisdom may be defined as a complex trait with several domains, including prosocial attitudes and behaviors (compassion, empathy, and altruism), social decision making or problem solving, capacity for self-reflection and understanding/insight, decisiveness, acknowledgment and acceptance of uncertainty, emotional regulation, tolerance of divergent value systems, openness to new experience, spirituality, and a sense of humor. What unites these components is their utility for the self (e.g., greater well-being) and for others (better relationship with others and serving the common good). The cumulative experience of life with age may promote some of the dimensions associated with wisdom. Some, although not all, studies suggest an increase in several domains of wisdom with aging that may be important for an older adult's ability to survive and even thrive in spite of worsening physical health. The Grandmother Hypothesis suggests that wisdom transmitted to younger generations may provide species fitness advantage and help neutralize the evolutionary pressure associated with loss of fertility in old age.

Recent research has also shown that wisdom has a strong inverse relationship with loneliness and may thereby protect against the deleterious effects of loneliness on medical morbidity and mortality. Although sometimes wisdom is contrasted with knowledge and "book learning," there is emerging evidence that key components of wisdom,

Telegram: @medical_k

www.konkur.in

such as empathy, compassion, and self-compassion, may be enhanced with compassion training, mindfulness, and other contemplative interventions.

Spirituality and Religiosity. Religious and spiritual practices are reportedly associated with greater well-being as well as better health outcomes throughout the lifespan. It may be argued that *religiosity* is better conceptualized under the umbrella of positive environmental factors (see next section) as the term *religiosity* is usually reserved in reference to involvement in organized religion and thus has an inherent social connotation, whereas spirituality can be personalized. However, religiosity ultimately rests on the beliefs and behaviors/choices of an individual. The term *spirituality* refers to an internal experience, that is, the degree to which one's personal beliefs, thoughts, and behaviors focus on transcendent topics such as the meaning of life, belief in a higher being, power or level of consciousness, awareness, or existence. Religious and spiritual practices are associated with positive outcomes such as greater well-being as well as better health outcomes. These positive effects of religious practices may partially rest on the emotional support derived from the religious community. Religious and spiritual beliefs also tend to confer a sense of optimism. Spirituality has been reported to increase with age.

Positive Environmental Factors

In addition to intrapersonal positive psychological traits, the interaction of the person with the environment and the nature of that environment also impact the likelihood of positive outcomes. These environmental factors are described below.

Social Engagement and Support. *Social Engagement* refers to integration into a social network or social participation—that is, how well-integrated one is into a social network. Within this construct are the number and quality of close relationships, the frequency of socialization, and the degree to which one finds meaning or pleasure from social integration/interactions. A related construct of *social support* refers to the degree to which other people are available for emotional and physical support. Empirical research has shown that the quantity and quality of one's social relationships are associated with better mental and physical

Telegram: @medical_k

www.konkur.in

health outcomes, including lower mortality, as well as more specific health outcomes such as lower prevalence of hypertension, cardiovascular disease, dementia, depression, anxiety, and substance use disorders in young and old adults.

Family Dynamics. A particularly influential form of social engagement and support is the family. There is a large amount of empirical literature showing that family dynamics and the degree of a supportive family environment affect mental and physical health, including symptom severity, treatment response, and recovery.

Other Environmental Factors. Access to quality physical and mental health care, as well as environmental factors such as availability of safe parks and walking paths, community centers, and access to grocery stores for healthy eating alternatives, can promote or discourage physical activity and exercise, nutrition, and stress reduction, especially in older adults.

BIOLOGY OF POSITIVE PSYCHIATRY

As noted above, psychiatry, as a branch of medicine, is rooted in biology, and so is positive psychiatry. Biology of relevant constructs includes neuroscience as well as genetics and epigenetics involving interactions among genes, environment, and structure and function of the brain. This type of research has implications for developing biologic interventions to enhance positive traits such as wisdom, resilience, and optimism, and thereby benefit mental and physical health. Work on biologic aspects of PFSFs has accelerated during the past decade, but there remains an obvious need for additional investigations in this arena.

Potential Biomarkers of Positive Mental Health

Allostatic load and telomere length are among putative biomarkers of stress and aging but can also be conceptualized as potential biomarkers of well-being in reverse.

Allostatic Load. Allostatic load reflects the body's cumulative physiologic response to frequent and sustained exposure to environmental stressors; it represents dysregulation of one or more

Telegram: @medical_k

www.konkur.in

biologic systems, multiple pathways to disease, and the cumulative cost of antecedent challenges which together can serve as an indicator of morbidity, as well as affecting cognitive functioning and psychological factors. There is no single measure of allostatic load, but a commonly used composite includes systolic and diastolic blood pressure, body mass index, serum cholesterol (with an emphasis on HDL), and plasma norepinephrine and epinephrine.

Telomere Length. Telomere length is an indicator of biologic age and may represent a cumulative index of the number of cell divisions and a cumulative record of exposures to genotoxic and cytotoxic processes such as oxidation. Telomere length is maintained by the enzyme telomerase, and there is some preliminary evidence that healthy lifestyle changes, as well as psychosocial stress reduction interventions, can increase telomerase activity.

Oxidative Stress. Oxidative stress, caused by an over-production of free radicals or underproduction of anti-oxidant molecules, damages DNA, protein, lipids, and other macromolecules in many tissues, with the brain being particularly sensitive. Oxidative damage to cellular components by free radicals may be an important component of the aging process. Thus, prolonged or repeated exposure to oxidative stress may accelerate aspects of biologic aging, leading to greater comorbidity and mortality.

Inflammation and Immune Function. Neuroinflammation and immune function also relate to several PPSFs. For instance, a low level of optimism has been reportedly associated with increased inflammation markers. Reduced personal mastery resulting from chronic stress may provoke excessive activation of the autonomic nervous system, which may, in turn, affect immune functioning. Several studies report direct associations of engagement in pleasant events with better health, including reduced plasma concentrations of inflammatory biomarkers and lower catecholamine response to stress.

Genetics and Epigenetics. Genes clearly play a role in determining the lifespan and health status in older age. Many PPSFs are also influenced by genetic factors. For example, resilience and optimism are

Telegram: @medical_k

www.konkur.in

both partially heritable. Beginning in development, an individual's genes and their interactions with environmental factors may shape the neural circuitry and neurochemical function expressed in PPSFs. Various genetic polymorphisms affect a person's limbic reactivity and prefrontal-limbic connectivity. Adaptive functioning of fear, reward, emotional regulation, or social-behavior circuits underlies a resilient person's capacity to face stress. Stochastic epigenetic changes occurring during brain development that drive resilience and hardiness may affect response to periods of high stress.

About 20% to 30% of the variability in human lifespan appears to be attributable primarily to genetic factors. Overall, longevity seems to be promoted by an absence of genes that predispose people to diseases rather than by the presence of "life-extending" genes. The risk for cognitive impairment in older age is clearly raised by the presence of the ApoE4 allele, but this may be attenuated by higher educational attainment or greater "cognitive reserve." In short, genetic vulnerabilities may be amenable to modification through intentional or incidental environmental changes.

Neuroplasticity Across the Lifespan

Throughout most of the history of neurology, the prevailing assumption was to see childhood as the period of brain development and later life as a period of neurodegeneration. But the past two decades of neuroscience research have shown reality to be more complex as both processes, development, and degeneration, occur throughout the lifespan. For example, adolescence is a period of programmed pruning of neural synapses, yet new synapses and even neurons can form in certain subcortical regions in older adults who stay active physically, cognitively, and psychosocially.

There are now convincing empirical demonstrations that neuroplasticity, with associated brain growth and development, continues into old age. Mechanisms underlying neuroplasticity include compensation for aging-associated degenerative changes (e.g., involvement of larger numbers of neuronal networks in the performance of activity) as well as synaptogenesis, increase in the number of dendritic spines, and even neurogenesis in selected areas of the brain such as the hippocampal dentate gyrus and periventricular region. Such neuroplasticity is related less to the genes inherited than to the behavior,

Telegram: @medical_k

www.konkur.in

attitude, and environment that affect the expression of those genes. It is this neuroplasticity that may enable PPSFs to affect an individual's well-being throughout the lifespan, although the brain is admittedly less plastic in later life than it is in childhood and early adulthood.

INTERVENTIONS

Research on interventions aimed at promoting PPSFs is in the early stages but seems highly promising. Treatment trials have shown beneficial effects of behavioral strategies buttressing resilience, changing attitudes toward aging, or incorporating meditation on outcome measures such as well-being, as well as alcohol consumption, biologic response to stress, and mortality rates in older adults. There is considerable diversity in the types of psychosocial or behavioral interventions reported, which include writing gratitude letters, practicing optimistic thinking, acts of kindness, replaying positive experiences, socializing, life review, mindfulness, cognitive behavior therapy, life coaching, goal training, and forgiveness therapy. Cognitive behavior therapy has been shown to be effective in enhancing optimism and facilitating the reappraisal of traumatic events in a more positive light. Increasing optimism has been found to increase adherence to pharmacotherapy in formerly pessimistic individuals. Interventions aiming to improve social engagement, while not specifically targeting depression, appear to have antidepressant effects in older people. Studies of the longer-term effects of meditation have reported reduced mortality rates in older adults at risk for negative cardiovascular outcomes. A number of randomized controlled trials have shown the efficacy of psychosocial interventions to enhance components of wisdom such as empathy and compassion, emotional regulation, and spirituality.

Interventions to Enhance Healthy Aging

A key component of positive psychiatry in the context of working with older adults is the concept of successful or healthy aging. The quest for "antiaging" therapies and interventions has gone on for thousands of years, with as yet little in the way of a "cure" for aging being found. However, there are interventions that can delay the onset of disability and disease and prolong "healthspan." In contrast to earlier assumptions,

Telegram: @medical_k

www.konkur.in

many of these interventions, such as physical exercise, appear to produce benefits even among older adults.

Lifestyle Interventions. Lifestyle behaviors are a logical place to start when thinking about enhancing positive outcomes in older people. Physical exercise, proper nutrition, activity participation, and regular health screenings and vaccinations are among the most powerful and modifiable predictors of the health span. In addition to the positive effect of healthy behaviors on the cardiovascular system, recent research has provided compelling data that improvements in brain structure and functioning can be attained from improving lifestyle habits.

PHYSICAL ACTIVITY. The axiom "what's good for the heart is good for the brain" has gained research support in recent years. There is strong evidence from randomized controlled clinical trials conducted among sedentary older people that increasing aerobic physical exercise can enhance performance on cognitive tests. Together, the empirical literature suggests that initiating exercise participation in later life may have significant effects that extend beyond physical outcomes and include cognitive and emotional improvements.

Using animal models and examining the biologic effects of exercise, it is likely that physical activity has multiple pathways leading to improvement in cognitive and emotional health. By reducing hypertension, the risk for cerebrovascular diseases decreases. By reducing obesity, stress on the skeletal system is diminished. Physical activity may also have the secondary benefit of increasing social engagement. Fall risk may be decreased by increasing muscle mass. Research from animal models suggests that at the cellular level, exercise may provide a mild stressor that may act as a kind of "inoculation" against other kinds of stress and may promote neuronal growth.

The Centers for Disease Control and Prevention suggests that adults engage in 3 to 5 days per week of moderate-intensity exercise (equivalent to brisk walking) for 30 minutes or more, stretching every day, and strength-building activities 2 to 3 days per week. Only about one-third of Americans meet the minimum exercise recommendations, and the prevalence of meeting these criteria decreases with age. At particular risk for not engaging in recommended levels of physical exercise are

Telegram: @medical_k

www.konkur.in

older people from ethnic minorities, who have lower educational attainment, or who have sub- or supernormal body mass indices.

A central challenge to increase exercise participation is identifying the barriers to exercise in routine life. The “walkability” of the built environment is an important consideration for enhancing engagement in physical activity, especially for older adults because they appear to prefer walking over other exercises.

DIET AND NUTRITION. Diet and nutrition are clearly related to health and other positive outcomes, and no other strategy for healthy aging has received as much research support as caloric restriction. Caloric restriction has been examined in worms (Caenorhabditis elegans), rodents, primates, and humans. Reducing caloric intake has been associated with increasing the lifespan of certain strains of mice and primates. In addition to extending the lifespan, deceleration in other aging phenotypes accompanies caloric restriction. The exact mechanism of caloric restriction is unclear, but it may involve reducing the rate of metabolism, perhaps limiting cellular wear and tear. Whether and how calorically restricted diets can be safe and palatable in humans remains to be seen; however, there are ongoing studies examining the impact of caloric restriction in older, overweight, or obese adults.

The content of dietary intake is also of interest to promote health, and in an epidemiologic study, a “low-risk” diet has been recommended one that includes a higher ratio of polyunsaturated to saturated fats, high in cereal fiber and marine fatty acids, low in glycemic load, minimal trans fats, and multivitamins. Additionally, moderate alcohol drinking (1 to 2 drinks per day), especially red wine, appeared to be better in the Nurses’ Health Study. As with exercise participation, only a minority of older adults conform to such a diet, and a growing proportion of people, including older people, are obese. Indeed, the rising incidence of obesity in the United States may significantly slow the rate at which life expectancy increases over the next 30 years–that is, obesity may decelerate the dramatic gains that have been made in life expectancy. Practitioners working with older adults need to provide dietary education, explaining the risks associated with unhealthy diets and encouraging healthier alternatives.

www.konkur.in

Biologic Treatments. The potential for biologic treatments in positive psychiatry is largely awaiting further research, but there does seem to be potential for advances in this arena. Recent research suggests that it might be possible to use neurobiologic approaches to enhance resilience in the context of anxiety and mood disorders. With an increased understanding of the neural circuitry underlying resilience, new interventions may also be developed using findings indicating that individuals can be trained to modulate their own brain activity with the help of real-time functional magnetic resonance imaging (fMRI)-based neurofeedback. Biologic interventions may be developed on the basis of an improved understanding of neuroplasticity as well as gene variations related to positive traits. In addition, findings from animal and human studies might eventually yield new pharmacologic agents that can maximize the adaptive function of the HPA axis as well as monoamine, neuropeptide, and other neurochemical stress response systems.

Public Psychiatry

56.1 Public and Community Psychiatry

NIDAL MOUKADDAM, M.D., PH.D., AND ASIM A. SHAH, M.D.

"I am proposing a new approach to mental illness and to mental retardation. This approach is designed, in large measure, to use Federal resources to stimulate state, local, and private action. When carried out, reliance on the cold mercy of custodial isolation will be supplanted by the open warmth of community concern and capability. Emphasis on prevention, treatment, and rehabilitation will be substituted for desultory interest in confining patients in an institution to wither away."—John F. Kennedy, Message from the President of the United States Relative to Mental Illness and Mental Retardation, February 5, 1963.

WHAT IS COMMUNITY PSYCHIATRY?

Community psychiatry, historically, blossomed and evolved in parallel with the push for deinstitutionalization and closure of large psychiatric facilities in the 60s and 70s. The overarching vision included geographically centered coordinated care for the most vulnerable and severely ill members of society. The target population typically suffers from triple serious illness: psychiatric, medical, and addictive, and often has a history of traumatic life experiences, compounding the treatment complexity. Based in public sectors, community psychiatry has evolved to encompass a diffuse network of treatment locations and modalities that diverge from its original character. Since the passage of the 2010 Patient Protection and Affordable Care Act (ACA), the experience of public, social, and community psychiatry has been transforming, with multiple changes in behavioral health care delivery and conceptualization. The term public can refer to psychiatric programs, treatment, or institutions paid for by public funds or as objects of public policy, whether paid for or not. Traditionally, community, or public psychiatry contrasted with private psychiatry, the latter being the entrepreneurial practice of delivering services to individuals having some means of purchasing them. As discussed

Telegram: @medical_k

www.konkur.in

below, expansion in inclusion criteria of recipients of community psychiatry has led to changes in its theoretical and practical scopes.

Funding for public and community psychiatric services tends to be provided by federally legislated appropriations that are passed through state, county, and municipal government agencies (such as departments of mental health; substance use treatment services; children, youth, and family services; and public health, social services, education, adult corrections, and juvenile justice agencies). Ultimately, most public psychiatry and community services are provided by not-for-profit community mental health, substance use treatment, child guidance, social services, or health care organizations that either are funded by or subcontracted to government agencies. Thus, the very existence of public and community psychiatric services and the policies and resources determining how they are delivered are extremely dependent on legislative mandates and fiscal appropriations from all levels of public government.

Psychiatry practitioners and administrators working in the public sector must be knowledgeable and savvy concerning the laws, regulations, and funding mechanisms relevant to their services. There is recognition of the prevalence of substance use disorders, both as primary disorders (often in combination with mental disorders, that is, “co-occurring” substance use and psychiatric disorders) and as secondary disorders (when mental disorder[s] are the condition of the first onset of primary concern, i.e., “comorbid” psychiatric and substance use disorders), and community psychiatry clinical workflows must reflect the various layers needed for effective treatment.

THE ROOTS OF COMMUNITY PSYCHIATRY

The precursor for community psychiatry, described below, was termed *boarding out*. As early as 1864, Sir Arthur Mitchell, in his work titled “The Insane in Private Dwellings,” discussed how mental health care did not have to be limited to asylums and how this expansion did not necessarily have to relate to limited asylum bed capacity, but rather a true ability to provide proper community-based care. The term community, as historically applied to psychiatry, connotes the mental health status of a specific, geographically defined population in a specific geographical catchment area. It is synonymous in all respects with “not the state hospital” and is contrasted to institutional care, especially in the move to community mental health in the second half of the 20th century.

The concept of “boarding out” and living with family despite chronic mental illness was tested in Scotland in the late 1800s as well. A major survey of individuals with mental illness in 1862, based on 7,000 home visits, revealed that the number of people living in asylums was about equal to the ones outside asylums and that homelessness was a major issue, even at the time. The other trend that Mitchell described, even in 1862, was that individuals with mental illness suffered often precipitous socioeconomic decline, sometimes affecting their entire

Telegram: @medical_k

www.konkur.in

families. These discoveries were in parallel with epidemiologic mortality surveys of individuals with psychiatric illness in the community and with mortality surveys. They are also echoed in modern literature that gave rise to community psychiatry: one example is the thought that individuals with chronic psychotic disorders such as schizophrenia become less employable and end up in lower socioeconomic classes than peers of comparable age. The social drift hypothesis was re-explored using population, twin, and molecular genetic data, with the conclusion that the downward sociofunctional drift was largely due to genetic, not environmental influences, though the role of “social defeat” and trigger events preceding first psychotic episodes, has long garnered interest as a factor in desensitization of the mesolimbic dopamine system. Regardless of the reasons for this drift, the community psychiatrist often encounters complex patients with limited employment histories and limited social functioning, reflecting the impairments of negative and cognitive domains of schizophrenia.

The concept of chronic mental illness being compatible with a noninstitutional life rhythm was espoused by writers such as Susser, who outlined modern applications of the concepts in the 1960s and the experiment of community psychiatry in Salford, Britain. The goal was, and still is, to treat mental illness on an outpatient basis and, by providing psychosocial support as well as psychiatric care, to aim for full integration of individuals with severe mental illness (SMI) in society.

The term psychiatry originally described the medical specialty focused on the care of persons with mental illness in the state hospital setting. Its domain was strengthened by the dominant role of the medical superintendents of the state hospitals (who would eventually be called “psychiatrists”) and their medical colleagues in the latter half of the 19th century and the first half of the 20th century. However, in the era of community mental health in the latter half of the 20th century, the term exploded to cover a host of disciplines, and new personnel was recruited to staff the community-based supportive treatment systems that were supposed to take the place of the institutions. Nursing, social work, clinical psychology, various therapeutic specialties, and non-degreed direct care providers all became labeled as part of psychiatry. One of the most dramatic changes emerging since the late 1990s is the role of consumers of psychiatric services as providers in their own right through networks of peer-support services and advocacy initiatives. Family members of people with these disorders are also increasingly taking a more assertive role in treatment and support.

Different phases are noted in how mental illness was viewed in the United States: Colonial times and the early years of the Republic were the era of the poorhouse, during which the great majority of persons with mental illness found refuge or were confined for their own and others’ protection as part of local community management. Care and custody were the operative functions, and treatment was nonexistent. In the 18th century, the ideals of the Enlightenment formed the basis for a paradigm shift toward fostering a better life for persons with mental illness rather than condemning and isolating them, ushering in an era of

Telegram: @medical_k

www.konkur.in

“moral treatment” (aimed at restoring the capacity for ethical conduct) through a return to the pastoral rural environment of the preindustrial age (“the Retreat”). In the mid-19th century, the protection and moral rehabilitation of the mentally ill was scaled up and institutionalized through the pioneering work of Dorothea Dix, resulting in an age of the asylum, during which public inpatient facilities, generically called state hospitals in the United States, were constructed in every state. A century later, advances in medicine, psychodynamic psychiatry, biologic psychiatry, and cognitive-behavioral psychology, along with a remarkable policy consensus, moved federal legislation to shift from institutionally based care to an era of community mental health. Finally, as health care costs began to soar at the end of the 20th century, and as employer purchasers and government moved to create market-driven health care, mental health policy moved conceptually to tightly organized systems of care that focused on prevention, early intervention, and intensive community care for children with severe emotional disturbances and their families and community support and recovery for adults with serious, acute, and persistent mental illnesses. The policy and concept, although ideal, remain partially operational with the smooth provision of care constantly jostled by bureaucratic, regulatory, and economic potholes.

In the American colonies and in the early days of the Republic, the care of the mentally ill was modeled on the practices of 18th-century England, where the Enclosure Laws disrupted the rural social order and set thousands on the road to seek shelter and employment in the cities. People with mental disabilities were at a particular disadvantage. They were saved from vagrancy by confinement in poorhouses, prisons, and jails, along with criminals, debtors, and other people with disabilities. In the American colonies, most towns would establish a poorhouse, and persons with mental illness, especially those who were found to be disruptive, would be committed by the actions of local government to extended stays in them. It is not that there were no hospitals. The construction of a public hospital was first proposed in Virginia in 1766. The money was appropriated in 1770, and the Public Hospital at Williamsburg opened in 1773, which was the first public mental hospital in the colonies. In Massachusetts, McLean Asylum opened in Charlestown in 1818. The first large state hospital opened in Worcester, Massachusetts, in 1833.

The physician superintendents of these early hospitals were the reformers of the era, following the ideas of moral management put forth by the French reformer Philippe Pinel. Pinel believed that if people were removed from their urban environments, relocated to an asylum in a beautiful pastoral setting, engaged in agriculture and the trades, lived in close proximity with staff, and were treated with kindness, then soon they would fully recover from the behavioral changes that they manifested as a result of having lived in a stressful, demanding environment. Benjamin Rush, a signer of the Declaration of Independence and considered the founder of American psychiatry, applied many of these theories and methods of his own in the treatment of the insane in the years after 1783 in the Philadelphia Hospital.

Telegram: @medical_k

www.konkur.in

The great majority of those who experienced mental illness, however, were kept in poorhouses or jails under deplorable conditions and became a cause for reform. The Unitarian reformer, Dorothea Dix, had begun a 2-year survey of the conditions in which these people lived. In 1843, she compiled her findings in a Memorial to the Legislature of Massachusetts: “I tell what I have seen, to present the state of the insane persons confined within the Commonwealth in cages, closets, cellars, stalls, pens! Chained, naked, beaten with rods, and lashed into obedience!”

After the Massachusetts Legislature appropriated funds for a substantial expansion of the Worcester Hospital between 1844 and 1854, Dix traveled more than 30,000 miles, visiting hundreds of prisons, almshouses, jails, and hospitals, collecting data, and arousing public opinion to her cause. In 1848, with the example of federal support given to education, she sought federal support for national hospitals. President Franklin Pierce, who stated, “I cannot find any authority in the Constitution that makes the Federal Government the great almoner of public charity throughout the United States,” and vetoed the bill for federal support. Public mental health was, for the next century, exclusively in the hands of the states and the state hospitals that continued to be built only to be quickly filled and become hopelessly overcrowded.

Early American Psychiatry and Ties to the Community

It has been said that U.S. medicine reached a critical juncture toward the beginning of the 20th century. Science and medicine had established a strong alliance in the major university medical schools, and the profession had established powerful public credibility as breakthroughs transformed the practice of medicine. This has started the era of evidence-based practice. Psychiatrists were not at the forefront of this transformation, but they were profoundly affected by it. One of the most prominent psychiatrists of the period, was Adolf Meyer, and his life and career may be thought of as representative of what was happening to psychiatry. Meyer was born in Switzerland in 1866 and was trained as a neurologist. He came to the United States in 1892 and worked for 8 years in state hospitals in Illinois and Massachusetts. In this sense, he came from the ranks of the asylum psychiatrists who were the bulwark of the state hospital system that had, by that point, spread throughout the country.

The first public psychiatrists were state hospital superintendents, responsible for all institutional clinical and administrative functions. Within a few short years, the populations of state hospitals grew so that their treatment function was eclipsed by care and custody concerns. The superintendent became more of a manager and administrator than a treatment provider. The ability to organize and to bring order to the institution became a necessary skill.

The New York State Hospital system had established, in 1895, the Pathological Institute, which had two mandates: the study of mental diseases from the standpoint of cellular biology and the offer of instruction in brain pathology to state

Telegram: @medical_k

www.konkur.in

hospital physicians. The Institute sought to become the cutting edge of reform—not without opposition from the asylum psychiatrists, who were more oriented toward managerial and administrative concerns and clear demarcation of the diseased state of institutional inmates from the normality of functioning people in the community. Meyer became its director in 1901. When Henry Phipps endowed a psychiatric clinic at Johns Hopkins, Meyer was chosen as its first head. From Johns Hopkins, he played a leading role in American psychiatry for more than three decades.

Twentieth Century U.S.

At the beginning of the 20th century, the concept of dynamic psychiatry opened the possibility of psychiatry practiced in the community. Dynamic psychiatry blurred the distinction between health and disease and saw mental illness on a continuum. This allowed the center of attention for psychiatric practice to move beyond the institutions and to include troubled individuals in the early stages of illness. This approach elevated the significance of the life history and prior experience of each person. It was a short leap of faith to suggest that early community treatment might prevent the onset of SMIs that, up to then, had required institutionalization. The once strong bond between the asylum and psychiatry was unraveling. Dynamic psychiatry expanded the jurisdictional boundaries to include psychologically troubled individuals, as well as allegedly dysfunctional social structures and relationships. From 1880 to 1940, psychiatrists identified new careers outside of institutions. Psychiatrists articulated novel and sometimes bizarre theories and therapies; expanded jurisdictional boundaries to include not only mental disorders but also the problems of everyday life; proposed solutions for society's ills; and defined a preventive role. In retrospect, it was an over-reach that subsequently led to questions about the credibility of the field and its foundations. What had been hypotheses initially were interpreted by some as factual and often damaging (e.g., the so-called "schizophrenogenic mother," asthma as "a cry for help," etc.). It was also during this "pre-chlorpromazine era" that psychiatry alienated itself from the rest of medicine. Despite its good intentions, it was, in retrospect, gross overstatement based more on conjecture and opinion than a scientific basis.

Meyer was a leading figure in advocating "a fresh and courageous pragmatism" and held "a biological conception" of human beings: "We must…accept the statement that all mental activity must have its physiological side and its anatomical substratum." He developed a genetic-dynamic or developmental approach to mental illness, which he named psychobiology. He stressed the interaction of the organism with its environment and defined mental disorders in behavioral terms, tracing their origins to defective habits. He recognized the importance of consumer advocacy and supported Clifford Beers, a former mental patient, who wrote a celebrated work, A Mind That Found Itself, and who founded the Mental Hygiene movement.

Telegram: @medical_k

www.konkur.in

Meyer was an empiricist, urging his colleagues to assemble and catalog facts. He was not a theoretician or a systematizer. Perhaps he realized that biology did not yet have the scientific tools to construct adequate theories about human mental processes. In this regard, he did not favor Sigmund Freud and what he viewed as the tendencies to dogmatic pronouncement. The eminent social historian of American mental health policy, Gerald Grob, observed that "psychoanalytic concepts…had far greater influence on culture and thought than on medicine in general or psychiatry in particular." This seems to overstate the case, given the great enthusiasm for psychoanalysis that came after World War II and that dominated popular perceptions of psychiatry.

On the eve of World War II, as Meyer retired, public psychiatry had advanced on three fronts. First, research institutes and psychopathic hospitals were developed alongside the state asylums in which research and training would benefit the care of persons with mental illness. These hospitals and institutes had limited success in that their research efforts to establish the efficacy of psychodynamic treatment progressed slowly, and they suffered a degree of mission drift away from the seriously and persistently mentally ill in the asylums and toward less severe mental health problems in the community. Second, an active consumer advocacy movement began in the founding of the National Committee for Mental Hygiene in 1909, which developed into a national movement focusing first on the plight of individuals in the asylums and then on mental health issues in the community. Finally, the ideas of dynamic psychiatry made it possible to think of the various stages of mental illness and the possibility of the prevention, amelioration, and potentially even cure of mental disease.

The 1950s were a time of great therapeutic optimism. Biologic psychiatrists pointed to the efficacy of drug therapy; their psychodynamic colleagues could point to psychological, psychosocial, and environmental therapies that would reach the most severely disabled institutionalized patients. Milieu therapy (the therapeutic community) arose in this period and had much in common with moral therapy. It appeared that medications were going to allow patients to engage in the therapeutic community, and then other innovations, such as unlocked wards and partial or day hospitals, were going to help some chronic patients transfer to the community.

As all of this momentum for change was building, a remarkable partnership for political action was developing among Robert Felix, the head of the newly formed National Institute for Mental Health, Senator Lister Hill, and Representative J. Percy Priest. Hearings were held aimed at focusing public attention on mental health problems and thus strengthening the case for an enhanced federal role. The Mental Health Study Act was passed in 1955, creating the Joint Commission on Mental Illness and Mental Health (JCMIMH). That Commission's final report, Action for Mental Health, did not make a clear-cut distinction between individuals with serious and persistent mental illness and psychologically troubled individuals. Although the JCMIMH report was a compromise among the 26 participating

Telegram: @medical_k

www.konkur.in

constituency organizations, nonetheless, there was strong support for fundamental change. Faith in the effectiveness of treatment in community programs was based on belief in the efficacy of early intervention, psychodynamic theories, epidemiologic efforts to elucidate the prevalence of mental illness in the community, and the putative identification of environmental variables.

At the end of the decade, with a new administration with an aggressive domestic agenda, the National Institute of Mental Health (NIMH) convened the Interagency Task Force on Mental Health, which developed the Blueprint for Action and, more importantly, activated the political coalition that made President Kennedy's initiative possible. The final policy sidestepped the provisions recommended by the JCMIMH for the refurbishment of the state hospitals and the provision of acute institutional care for the most severely disabled and devoted its attention to community mental health clinics, which it recommended to be enhanced to comprehensive community mental health treatment centers—the community mental health centers (CMHCs).

The national program for comprehensive CMHCs was in place. For the next 15 years, grants flowed to the localities and then through the states to the localities to the new centers, and states proceeded to build two community systems while beginning the process of phasing out the old state hospitals. The immediate discovery was that the CMHCs were able to expand mental health services for the communities but were not at all prepared to care for persons with serious and persistent mental illness who had spent most of their lives in state institutions. The discharge of 90% of the state hospital population (the deinstitutionalization process) without adequate community resources available was chaotic and often precipitous. It led to a class of homeless and generally untreated or transinstitutionalized individuals (put into nursing homes, prisons, squalid rooming houses, and hotels, etc.) who deteriorated outside the state hospitals. There also arose a peripatetic subpopulation with serious and persistent mental illness who often had comorbid substance abuse and generally avoided any beneficial involvement in treatment for a significant portion of the early phase of their illness. However, the states, to varying degrees, were set on a course of dismantling state hospitals that were becoming increasingly expensive. As federal staffing grants to the CMHCs were phased out and state contract dollars replaced them, the states gradually narrowed the focus of the community programs to its priority clients—the former residents of the state hospitals. Special programming models were developed to provide supportive programming for them that focused on community support and rehabilitative approaches rather than clinical ones.

As community mental health programs developed, it became clear that psychiatrists were, for the most part, playing limited roles: reimbursement could not support them full time, and they gravitated to private practice models that were appropriate for individuals with less severe mental health issues. The psychiatrists who were involved in the early CMHCs were quickly outnumbered by practitioners from the other disciplines and often sidelined themselves in private practice models

Telegram: @medical_k

www.konkur.in

in which they could treat educated and functional people with relatively mild disorders. One tongue-in-cheek publication during this era described the "YAVIS" individual as the "ideal" psychotherapy candidate…Young, Attractive, Verbal, Insightful, Successful. Many psychiatrists and others in behavioral health gravitated toward this profile for their ideal caseloads. These practice models limited their ability to treat persons with severe mental health disabilities without appropriate outreach and supportive care.

ORGANIZED SYSTEMS OF CARE

The psychiatric hospital is a special target of health care corporations. Its profit margins are large, investment costs are low, inpatient psychiatric care is now widely insured, and the complexity (and perhaps ambiguity) of psychiatric diagnosis and treatment makes cost control efforts by insurers and the government difficult. In 1968, for-profit hospital chains were nonexistent in psychiatric care. In 1980, investor chains owned 25% of private psychiatric hospitals, and, just 2 years later, these corporations owned a full 43% market share. Between 1982 and 1983, the number of investor-owned psychiatric hospitals rose 42.5%, from 106 to 151. The increase was partly attributable to investor groups' acquisition of existing facilities, but the new construction of psychiatric hospitals, which grew 53.3%, accounted for most of the growth. "Ad-Psych" (Adolescent Psychiatry) units are so lucrative that corporations have closed units providing other types of services in order to establish the more profitable adolescent units. Admission data reflect the current domination of the private sector in the provision of adolescent inpatient psychiatric services. Lois A. Weithorn, in the Stanford Law Review, noted that in 1980, for example, private facilities admitted 61% of all adolescents who underwent psychiatric hospitalization; since that time, juvenile admissions to these facilities have increased substantially.

U.S. health care costs began to increase dramatically in the 1970s. By the end of the 1980s, they were spiraling. The article just cited by Lois Weithorn in the Stanford Law Review addressed the possible violation of children's rights posed by their involuntary hospitalization in commercially operated psychiatric hospitals. It documented a trend of which U.S. employers—and the insurance companies that they hired to administer their health benefits—were all too aware. While employee health care costs overall were climbing, behavioral health expenditures were increasing by 50% each year. Venture capital had discovered a chink in the armor of health care finance. Even though there were lifetime limits for mental health benefits, a substantial amount of money lay in those coffers. Psychiatric hospitals were relatively cheap to build and could be designed to be converted to older adult housing facilities once the gap was closed. The criteria for mental illness were sufficiently permeable, and standards of care were sufficiently undefined that decisions for hospitalizations were made on behalf of many patients when more considered judgments would have found other alternatives. In fact, many hospitals

Telegram: @medical_k

www.konkur.in

launched deliberate marketing campaigns to fill their beds, and many practitioners participated. The trend was an abuse. Its most cynical aspect was that benefit dollars that could have been devoted to the care of persons with SMI were quickly extracted—a $50,000 lifetime limit could be spent in 60 days of private hospital care—so that sick patients were discharged to the care of public sector agencies.

Although several examples of health maintenance organizations (HMOs) had demonstrated their effectiveness in improving the health status of enrolled populations for several decades, U.S. employers were reluctant to require their employees to sign up for a plan instead of the traditional indemnity (or fee-for-service) health insurance. However, the growth of behavioral health expenditures was so dramatic that they overcame their reluctance for this sector. Within a few years, an industry of managed behavioral health organizations was created by the contracting activities of human resources executives of the major U.S. corporations. The new companies were staffed by a corps of seasoned mental health professionals, most of whom had been prepared in the ranks of the community mental health movement. They introduced, in a business-like fashion, utilization review techniques reinforced by elaborate information and communication technology. They selected panels of providers who could be trusted to care for enrolled members without inappropriate or extended use of hospital or other expensive care. Their impact was dramatic: Within a few years, behavioral health expenditures stabilized, at least temporarily.

The success of the carve-out of behavioral health care inspired employers to apply their contracting techniques to the rest of health care. Even though in 1987, only 27% were in managed care, by 1995, 73% of insured employees were enrolled in some form of managed care. Simultaneously, in the early 1990s, President Bill Clinton undertook a health care reform that attempted to provide universal health care as a highly regulated public entitlement. The Clinton health plan was labeled “managed competition” as a nod to the rapid move to competitive health care markets. However, the originators of that term—an assembly of business and health care experts known as the Jackson Hole Group—were much clearer about an approach in which government and government regulation would play a minimal role.

Nonetheless, a health care marketplace was created in the course of the failed Clinton health care reform. A wide variety of health care entrepreneurs would organize providers to bring their products to the markets, and consumers were encouraged to make choices that would ensure the value of the care that they would receive. The employers, through their contracting practices, sought to apply the principles of industrial organization to health care delivery to advance the ideal of organized systems of health care that were accountable and attractive to value-driven consumers. Although certainly, some excellent health care delivery systems have developed, most have fallen far short of these ideals in a full array of organizational structures. All of these structures and models fell under the term “managed care.”

Telegram: @medical_k

www.konkur.in

In the early 1990s, managed care's utilization review techniques and benefits had restrained providers; HMOs and other plan types restructured health care delivery; the insurance industry transformed itself, acquiring HMOs and creating a new array of "products" for employers to purchase; risk was cascaded to hospitals, in many cases making them insurers and encouraging them to consolidate their positions in physician hospital organizations (PHOs); and physicians reorganized their practices into independent practice associations (IPAs) and multi- and single-specialty groups. By the mid-1990s, the rise of health care costs leveled off (temporarily), but there was widespread dissatisfaction among consumers and the rest of the system. By 2000, many of these measures were relaxed. Instead of benefits that restrained professionals, copays for consumers restrained their utilization. Employers encouraged broader networks, preferred provider organizations, and eliminated gatekeeper access to specialists. The insurance industry consolidated itself through cross-market mergers and large national contracts.

Quality and accountability began to dominate the health care market by the end of the 1990s, and consumers were encouraged to look to quality ratings by major accreditation organizations in making their choices. Managed care has had an indelible impact on the U.S. health care system, introducing issues of quality and accountability, reinforced by the Institute of Medicine's report Crossing the Quality Chasm.

How Community Psychiatry Became Its Current Self

As the process of deinstitutionalization proceeded and patients were moved from state hospitals to care in community programs, the financing also moved from institutional budgets to the categorical budgets of the state mental health agencies to fund the community programs. As employers moved dramatically to managed care in the 1990s, however, state Medicaid agencies followed suit and contracted with the Behavioral Health Managed Care Organizations (BHMCOs) to manage their mental health benefit. States quickly realized that by moving mental health categorical dollars into their Medicaid program, they could leverage Federal Financial Participation (FFP) into their state's general fund. Almost all of the states shifted large portions of their mental health budgets for direct services into the Medicaid program—hence the substantial increases in mental health funding. However, these services ended up in the stewardship of Managed Behavioral Health Organizations (MBHOs), whose products tended to be modeled on private-sector mental health care for general populations. Currently, patients are diffuse in communities, with the fragmentation of U.S. social welfare programs that is reflected in disparate payment systems.

Three contemporary trends have influenced the conceptualization of public and community psychiatry in the daunting climate facing U.S. health care. The first is the realization that the effect and pervasiveness of psychiatric disorders impose a

Telegram: @medical_k

www.konkur.in

global burden on society. The second trend has been the shift in funding for public psychiatric services from state expenditures, tied to the historic funding for state hospitals, to Medicaid, a health insurance model driven by the “medical necessity” for intervention. Finally, the power of reform efforts in general medical care and psychiatry have led to increasing demand for the use of evidence-based interventions defining quality, safety standards, and efficiency in the delivery of health care.

The first trend—the recognition of the burden of these disorders—can be most directly linked to a landmark study called the Global Burden of Disease. This study, funded by the World Health Organization (WHO), the World Bank, and several foundations, considered the leading causes of disability and premature death worldwide as a result of various health and situational problems. Of the ten leading causes of disability worldwide, five are neuropsychiatric, with the leading cause of disability being depression. When considering the leading causes of healthy years of life lost using the concept of disability-adjusted life years (DALYs), which reflects premature death and disability, depression was found to be in the top 3 in the world and in the United States. Mental health disorders were the fourth most costly health problem in the United States in 2000, 2004, and have only gotten worse in recent years. Schizophrenia, though not a highly prevalent disease, afflicts a substantial burden. When the cost to society of trauma-related disorders (which include post-traumatic stress disorder [PTSD]) are added in—and exposure to traumatic stressors has been found to play a role in both causing and moreover severely worsening most psychiatric disorders—the cost to the United States is ~50% more than the annual cost of heart disease and almost double the annual cost of cancer. New WHO data indicate that rates of various mental illnesses are increased to 22.1% in areas with war conflict (depression, anxiety, PTSD, bipolar disorder, and schizophrenia).

Second, after a period of critical evaluation of U.S. medical practice, the IOM, in its 2001 report entitled Crossing the Quality Chasm: A New Health System for the 21st Century, brought much clarity. This is a call to American medicine to reform inadequate service delivery systems and to apply effective practices systematically. It documented the need for a fundamental overhaul of the entire U.S. health care system, addresses the problems caused by insufficient quality in the health care system, and offers a road map for creating a new health system. A key principle in enhancing the quality of health care services is that treatments and practices must have a clinical and scientific evidence base in order to justify their utilization and costs. The Quality Chasm report was a primary influence among a series of reports from the IOM and other authoritative agencies in the two decades that laid the foundations for the health reform that has been codified in the ACA (2010).

Third, ACA-related changes to financing brought about an avalanche of changes in community mental health provision. The role of Medicaid in shaping public services for people with mental illnesses is difficult to overstate. For state governments, the appeal was almost immediate. When the states assumed the

Telegram: @medical_k

www.konkur.in

onus of care for people with mental illnesses, largely through the mechanism of state institutions, 100% of those expenditures came from state budgets—competing with all of the other priorities facing state legislatures. Medicaid, which is a state-federal partnership, allows states to shift between 50% to 80% of their cost for covered services to the federal budget. More recent federal laws and regulations mandating parity in eligibility and reimbursement for mental health (compared to medical/physical health) have attempted to direct more services to more individuals with mental illnesses. The Triple Aim: Better Care, Better Health, Lower Costs, has been the goal all along. Better Care refers to evidence-based psychiatry, integrated with primary care, in the context of coherent health care delivery systems.

The developments leading up to the ACA, as well as the statute itself, have laid the groundwork for the agenda of improving health care for public and community psychiatry. This is to be accomplished by CMHCs applying for status as Community Health Centers, or Federally Qualifies Health Centers (FQHCs), as well as strengthening the behavioral health services in the existing FQHCs. Fidelity to research-validated practices in implementing treatment and replication as the therapeutic model is aimed for, with some funding funneled through the Patient-Centered Outcomes Research Institute (PCORI). The ACA included the concept of a “Primary Care Residency” program to be based in community-based practices as Teaching Health Centers, including the FQHCs and CMHCs. Psychiatry is included as a specialty in those programs.

THE RECIPIENTS OF COMMUNITY PSYCHIATRIC CARE

Federally Qualified Health Centers (FQHCs) deliver care to the underserved populations in the United States. According to the Health Resources and Services Administration (HRSA), the health center program has 255,000 full-time staff and serves nearly 29 million patients. The number of patients served has tripled since 2000. More than half of FQHC patients belong to racial and ethnic minority groups, and almost 90% live in poverty, according to HRSA data.

At its inception, community psychiatry aimed to help communities as a whole, but over the years, much operationalization of what qualifies for treatment in community settings has taken place. Initial selection criteria reflected the population that was admitted to institutions and seeking care. Subsequent cost-cutting measures and refinement of workflows and protocols led to many restrictions but also much heterogeneity. The basic definition of serious mental illness aims to include the most vulnerable populations. In the Unied States, the term ***serious mental illness*** (SMI) originated from the National Plan for the Chronically Mentally Ill, a product of the President’s Commission on Mental Health (1978). SMI typically involves symptom severity and functional disability. Attempts to refine the concept of SMI resulted in redefinition by Substance Abuse and Mental Health Services Administration, published in the ADAMHA Reorganization

Telegram: @medical_k

www.konkur.in

Act, Public Law 102–321, 1992, but states are free to use modified definitions, and more than 20 of them have adopted their own definitions. SMI definitions vary in Europe as well. Those definitions shape the funding received by organizations delivering community psychiatry in various states. The only common element of all SMI definitions is a psychiatric diagnosis, but the nature of the psychiatric disorder, disability, and duration vary by location. Psychotic disorders appear inclusionary in reviewed criteria, with mood disorders (major depressive and bipolar disorders) being the second most common category included in SMI classifications. Personality disorders are deemed by many to meet disability and duration criteria for SMI but are not accepted as entry diagnoses in some localities. This heterogeneity could have significant impacts on the purity and consistency of psychiatric nosology used in communities. This may lead to erroneous or exaggerated diagnoses of psychotic disorders, mood disorders or omission of substance-induced disorders, neurocognitive disorders, and organic causes of mental illness.

Financial Thresholds

Financial threshold to define recipients of community psychiatry services have also been used. Over the past two decades, entry into community programs has been linked to dual criteria incorporating both diagnosis and financial status. Recipients of community services often do not meet criteria for Medicaid, but after the ACA-related Medicaid expansion, some were able to get coverage; thus, coverage for community psychiatry now includes a spectrum of funding from uninsured, 100% to 138% of poverty/ eligible for subsidized private coverage, and Medicaid-eligible. Medicaid-only enrollees can be categorized as foster care young adults (ages up through 21), very–low-income adult parents, low-income peripartum women, or Supplemental Security Income (SSI) recipients. Income below 138% of the federal poverty level, meeting SMI criteria, and uninsured status are often needed to benefit from indigent resources. *Thus, community psychiatry now serves a larger swath of the population than it did at its inception in the 1960s*. It now serves individuals with SMI, but also individuals one could think of as the “working poor.” This is the group of workers who purchase health insurance because they do not receive health benefits from their employer, earn too much to qualify for Medicaid, and do not qualify for Medicare. With this expansion, the kinds of services needed and the spectrum of issues encountered become more variable, not limited to SMI, and therefore need a careful reassessment of the face and identity of community psychiatry.

THE ROLE OF THE PSYCHIATRIST IN COMMUNITY PSYCHIATRY

Telegram: @medical_k

www.konkur.in

The psychiatrist, in their role as the medical specialist, trained in the discipline of medical sciences, had a very narrow focus, exercising medical and legal authority to take defined actions on behalf of individual patients. In the community psychiatry paradigm, the public psychiatrist practices psychiatry in publicly funded services and carries out programs that are mandated by public policy, interfaces with other team members, and is the team leader in the care of the patient with mental illness. As a public and community psychiatrist, they are engaged with a specific geographically defined population using community programs for the care of individuals with mental illness in order to improve the health of the community as broadly defined.

Psychiatrists in the public sector should work within a team that includes professionals from several disciplines (e.g., psychology, social work, nursing, occupational therapy, rehabilitation or addiction counseling, social services, housing, and employment specialists) and non-degreed direct care workers (e.g., bachelor's degree–level counselors or case managers, high school graduate, indigenous outreach workers, peer-support specialists, and family advocates), each of whom brings unique skills and experience to address the varied needs of people with severe and persistent mental illnesses. The team, rather than any single individual, assumes responsibility for the ongoing care of each patient across the many levels of services and often for many years. Its success is based on effective communication and coordination. Communication and coordination should be explicitly focused on the individual's (i.e., patient's and/or family's) stated goals, as well as on the community resources available and the team's technical and logistical capacities. Maximizing the individual's motivation to participate actively and productively in a comprehensive treatment plan that is patient-centered and collaborative is essential.

Psychiatrists can play four primary roles in multidisciplinary psychiatric rehabilitation teams: (1) conducting psychiatric diagnostic and treatment evaluations with significant involvement from members of the team; (2) providing thoughtful pharmacotherapy; (3) coordinating care with physical medicine in order to promote both physical and mental health; and (4) serving as the team's medical director, mentor, sometimes clinical supervisor, peer, and colleague.

The psychiatrist is being called upon to play a special role as the project or program medical director—with the attendant responsibilities of monitoring the medical safety and well-being of all patients and establishing or supporting management and clinical procedures that support quality of care and a cohesive treatment team. As the team's clinical Mentor, or simply as a team member, the psychiatrist serves as a role model for compassionate and professional behavior in relation not only to patients but also to all other team members. Formal or informal leadership is especially important when psychiatry residents and medical students work on a team as a training experience. The team psychiatrist serves not only as a mentor and a role model for the core aspects of psychiatric practice but also should demonstrate the values and skills necessary to integrate psychiatry within

Telegram: @medical_k

www.konkur.in

the framework of psychosocial interventions that are multimodal, community-based, and longitudinal.

The connotation associated with public and community psychiatry has been synonymous with care for the poor and underprivileged, care for special populations normally not attended to by the private sector, overwhelmed systems, low reimbursement and inadequate resources, inferior and unresponsive care, and a final common pathway for individuals no longer able to afford private care. This is not for want of their providers' dedication: it is the paucity of the physicians' numbers and the general public neglect of this sector. The patients of public and community psychiatry as a group lack the most basic resources to sustain themselves (food, clothing, housing, financial support, social support, etc.), and they are arguably the group least likely to be able to advocate for themselves and to have the capacity to recover from this default position. The needs of the patients, the inadequacies of the delivery systems, the lack of an adequate workforce, and the lack of coverage make the sector of public and community psychiatry a poster child for the attention of the ACA reforms. It also makes the practice of community psychiatry both noble and challenging. The shift from a narrow focus on the treatment of a solo therapist to a broader psychiatric rehabilitation model, and now to models that stress the recovery of the individual, requires solid training (and continuing education) and hard work, as well as a combination of personal qualities, competencies, and expertise that have been summarized as "persistence, realistic optimism, a collaborative style, teaching ability, and networking and system coordination skills."

A major challenge to psychiatrists serving adults who have the dual burden of mental illness and socioeconomic disadvantage is the identification and enhancement of the psychological and sociocultural resources that can promote illness management and reintegration in a support system. The goal, of course, is recovery with the help of fully operational programs of assisting adults with severe and persistent mental illness to make the best possible adjustment in the least restrictive public and community settings.

THE INPATIENT TO OUTPATIENT AND COMMUNITY PSYCHIATRY CONTINUUM

Community psychiatry best exists in a system of care that attends to the full needs of persons with psychiatric illness. This need exists given the complexity and high frequency of co-occurring disorders in the patients typically served by community psychiatry teams. This would include inpatient care, emergency psychiatric services, substance use treatment modalities, social services, and functional rehabilitation support.

The ideal setup for treatment is that majority of treatment gets conducted on an outpatient basis, with flare-ups and crises being handled in transitional intensive programs and partial day hospitals, and for severe symptoms, in inpatient

Telegram: @medical_k

www.konkur.in

psychiatric units for short stays. Partial hospitalizations were found to be equivalent to inpatient care in meta-analysis. The advantage of preponderant outpatient treatment is both cost-driven but also mindful of the need to keep patients in their natural environment. An essential component for the success of community psychiatry is a linkage between various service components, so patients do not end up needing higher levels of care inappropriately. When patients are released, the cohesiveness of the conditions of release and careful considerations for re-entry in the community are essential to avoid re-hospitalization or treatment nonadherence. This area has had repeated formulas tried for the last two centuries, dating back to the state of Massachusetts in 1897. Economic drivers of decreased length of acute hospitalization overlay other factors that had driven community and social psychiatry to the forefront of psychiatry, namely optimistic beliefs that improved treatment options would lead to less need for acute care and that options for other conditions, such as addictive disorders, are available. Trends for treatment, however, show low usage of anticravings drugs and pharmacologic options for addictive disorders and poor treatment adherence to antipsychotics following hospitalizations.

The reality, however, is that there is a shortage of outpatient psychiatrists, a shortage of hospital beds, and many patients, up to 20%, awaiting hospitalization end up enduring emergency center boarding. Boarding affects patients with mental illness disproportionately compared to those with medical illnesses. Boarding is noted to be longer for patients with co-occurring illnesses, intellectual disabilities, aggression, and lack of insurance funding, all characteristics that tend to be more prevalent in community psychiatry samples. Once hospitalized, these patients have longer lengths of stays, and this is predicted by severity of illness, psychosis or bipolar disorder, polypharmacy, and need for emergency restraints/interventions.

The majority of caregivers for individuals with mental illness are family members, placing strain on communities. Care for a significant number of these individuals is poorly coordinated, and there is a recurring whorl of decompensation, emergency room visits, hospitalizations, various outpatient and sometimes residential programs, variable compliance and funding struggles with treatment, diagnostic confusion (e.g., schizophrenia vs. bipolar disorder, borderline personality vs. PTSD vs. depression, etc.), polypharmacy with lack of attention to guidelines or to metabolic consequences leading to the iatrogenic production of physical health problems for these individuals who then enter the cycle multiple times. Involvement with the judicial system is often part of the course. Thus, more recent focused attempts in community psychiatry have focused on jail diversion programs and better interface with the legal system. Additionally, within the legal system, there is a push to maintain treatment continuity and ensuring inmates receive psychiatric care consistently.

Case management remains a cornerstone of community psychiatry. The roles of the case manager include establishing rapport, coordinating with families, and connecting the patient to community resources. Some definitions of case

Telegram: @medical_k

www.konkur.in

management work are more holistic and focus on comprehensive care, with some models requiring case managers to work on social skills training and psychoeducation, for instance. The role of the case manager will also depend on the treatment model, with more intensive involvement, for instance, in ACT teams: in a comparison on ACT versus the standard care model, the intensity and frequency of visits varied, with 13 visits on average for the ACT team in the first 3 months, but 5 in the standard care model, and this difference reflects in the panel that a case manager can carry.

STIGMA AND DISCRIMINATION–AN OPPORTUNITY FOR COMMUNITY PSYCHIATRY

The Relationship Between Community Psychiatry and Health Maintenance

Community psychiatry has been evolving and adapting as psychiatry, as a discipline itself evolves. The worst-case scenario is the evolution of community and social psychiatry aspects to mere delivery of psychiatric services, with accompanying reductionism in diagnosis, treatment options, and views of mental illness. But this evolution also carries the potential to truly help our most vulnerable populations. The establishment of community psychiatry infrastructure and network can help further other needs of the population, including medical, substance use, and social. In that scope, community psychiatry, a branch of social psychiatry, can also serve as a springboard for wider wellness and theoretical, structural changes in health care by linking the social, psychological, and biologic spheres. In fact, with changes in managed care reimbursement and restrictions imposed by newer forms of health care, it is suggested that private psychiatry is starting to veer toward the models initially pioneered by community psychiatry. The historical separation of psychiatry from the rest of medicine, partly self-imposed and partly extruded by mainstream medicine, will hopefully be corrected as delivery systems change and as greater knowledge comes to influence more focused and effective interdisciplinary efforts.

The elements that make community psychiatry structures (in its more ideal form) a desirable model are: community psychiatry often involves teamwork with physicians, mid-level providers, nursing and case management, social work staff. These teams often interact with the legal system and families and (again, in ideal circumstances) with the patients' medical teams. Additionally, community psychiatry often interacts with and serves racial and ethnic minorities. This offers the multidisciplinary interactions our patients need. It is intuitive to match wellness initiatives, educational initiatives, and medical monitoring and social services measures to existing multidisciplinary infrastructures. HRSA aims for coordinated, comprehensive, and patient-centered care, integrating medical, dental, behavioral health, substance use disorder, and patient services. Individuals with SMI (schizophrenia, bipolar disorder, major depressive disorder) are at increased risk of

Telegram: @medical_k

www.konkur.in

cardiovascular disease-related death versus controls, as evidenced by a meta-analysis of 92 studies totaling more than 1 million individuals. Risk factors for mortality include antipsychotic use, elevated body mass index. Additionally, other types of diseases such as infectious, endocrine/nutritional/ metabolic, circulatory, respiratory were elevated in all SMI categories (including borderline personality disorder). Excess mortality from cancer is present in SMI as well. It is estimated that individuals with SMI die 8 to 10 years earlier than age-matched cohorts, often from natural causes. Therefore, it is essential that care systems combine as many interventions and preventive services as possible in order to truly help patients who often lack self-efficacy to mitigate their own problems. Integrative care, combining medical, social, and psychiatric, and improving treatment adherence to antidepressant and antipsychotic regimens may have some protective effect on premature mortality.

An example of the interface of medical and psychiatric management in the goal of comprehensive care for patients is the Delivery System Reform Incentive Payment (DSRIP).

DSRIP represents system transformation aiming to improve clinical management across settings, aiming for larger-scale population health improvement and, ultimately, reduction in avoidable hospital use. In Texas, DSRIP was designed as part of Medicaid waiver, §1115 of the Social Security Act. Nested in the 2011 Texas Healthcare Transformation Quality Improvement Program, DSRIP measures were spread and planned through regional health care partnerships (RHPs). It targets Medicaid enrollees and low-income uninsured individuals and includes regional assessments, goals/rationale for projects/expected results/annual milestones, and metrics. DSRIP aims to transform care delivery by integrating systems of care, delivering high-quality care that meets guidelines, and ensuring patients get prevention and primary care services. An obstacle to this, of course, is access, so one of the aims is to increase patient access, provide patients with a positive health care experience, and offer timely, proactive, coordinated medical home care.

DSRIP applies to mental health, which has a high chronic disease burden and extensive need for care navigation upon hospital discharge. This leads to unmet mental and behavioral health needs, which often get compounded by health care provider shortage and access to care. Some of the DSRIP mandates include follow-Up after Hospitalization for Mental Illness (FUH) within 7, then 30 days, and initiation of Alcohol and Other Drug Dependence Treatment on a continuum with hospitalization. Health systems have a choice in what measure to implement for their populations as well within the DSRIP context. The example of the Harris Health System in Harris County, Texas (the third largest county in the United States) was an alignment of elements needed for physical care and to meet guidelines for antipsychotic prescribing. The measures chosen were HbA1C and physical exams. Periodic reminders were built in the electronic health records. A

Telegram: @medical_k

www.konkur.in

second-level intervention was to add lipid profiles and a patient health questionnaire (PHQ-9) added.

Other opportunities for care alignment include using home visits by case management to screen for unfavorable social determinants of health, domestic and intimate partner violence, and other issues. A poorly explored area in community psychiatry and its nexus with medical care is the provision of end-of-life care. SMI patients have limited engagement in end-of-life planning and endure much suffering, often with concomitant physical and mental clinical decompensation. A potential role of community mental health and accompanying social services would be to promote advance directives and prepare patients for potential medical issues which they are not receptive to when they are ill.

From a broader perspective, psychiatry embedding in community centers can also be useful for prevention. Prevention is a natural impulse for any public health model. A disease or debilitating condition that can be avoided through early intervention and timely treatment can save a neighborhood or community and secure the overall health of the population. Health plans and community care systems should adopt carefully designed benefit packages for their enrollees, and that include preventive services and early interventions. The major public payers, Medicare and Medicaid, have incentive-based funding mechanisms encouraging some accountability for the most medically vulnerable patients. Smart public and community psychiatry will position itself in accountable clinical entities that are actively engaged in early intervention and intensive, individualized care management.

Application of the traditional public health concepts of primary, secondary, and tertiary prevention has been lacking in psychiatry but is highly possible. Primary prevention involves addressing the root causes of illness with healthy individuals, with the goal of preventing illness before it occurs. Secondary prevention involves the early identification and early treatment of individuals with acute or subclinical disorders or high-risk persons to reduce morbidity. Tertiary prevention attempts to reduce the effects of a disorder on an individual through rehabilitation and chronic illness care management.

Universal interventions are those intended for the general public, such as immunizations or media campaigns providing information about illnesses, early warning signs, and resources for health promotion and timely treatment. Selective interventions focus on individuals at higher-than-average risk (e.g., persons with prodromal symptoms or a family history of psychiatric disorders) to reduce morbidity by enhancing resilience and preventing the onset of illness. Indicated interventions target individuals who are experiencing impairment as a result of illness as early as possible in the course of the illness to reduce the burden of the illness on the individual, family, community, and treatment system.

Psychiatric disorders most often follow a course over time that begins with an often lengthy period in which prodromal or subthreshold symptoms or functional problems precede the full onset of an impairing disorder. Psychiatry integrated into

Telegram: @medical_k

www.konkur.in

primary care is in a position to identify these early symptoms and intervene effectively. In primary care, surveillance for very early universal intervention is possible, and selective interventions can be easily made as symptoms are recognized. Intensive psychiatric services can be organized in the form of indicated interventions when disabling symptoms appear to establish a path to recovery. A good example is early detection for individuals at high risk for psychosis and providing early interventions to prevent conversion to first break psychosis.

A public health-oriented strategy for disease and disability prevention will involve early identification and intervention in cooperation with consumers, families, health care professionals, and educators. Psychiatric professionals can play a key role by bringing their expertise to the development of appropriate screening, assessment, education, and treatment strategies that, if implemented on a wide scale, may reduce the burden of mental health disability and facilitate recovery. Psychiatrists also can become involved in the social marketing of prevention services and programs to add expertise and credibility to support legislation, regulations, and commercial investment that will provide the economic base necessary for broad-based prevention programs.

Prevention interventions have been found to be effective with adults with a variety of risk factors or preclinical problems. For example, women who have been raped are less likely to develop PTSD if they receive a five-session cognitive-behavioral treatment than if their recovery is left to chance. Men and women identified with subthreshold symptoms of depression in primary care settings are more likely to remain free from the full syndrome of depression or, if they do become clinically depressed, they will be able to recover rapidly with treatment if their standard medical treatment is enhanced by education about depression and learning skills for coping actively with depressive symptoms or stressors. This includes women who are at risk for postpartum depression, who have been shown to benefit from in-home cognitive behavior therapy in the first year after giving birth. Children who show early signs of severe behavioral problems (e.g., aggression, impulsivity, stealing) have been found to be less likely to become severely and chronically behaviorally impaired and antisocial when they and their caregiver(s) participate in therapeutic programs designed to enable the child and caregiver to deploy executive functions (i.e., anticipating consequences, inhibiting reactive behaviors, problem-solving) while simultaneously strengthening their attachment bond with each other.

The Medicaid program includes a mandated program for Early Periodic Screening Diagnosis and Treatment (EPSDT) that broadly covers very early intervention and extends services through the 21st year. States have been slow to meaningfully implement the periodic screenings and full use of the program because of the potential financial liability of the program to the states. Consent decrees have, in some cases, been used to expand these services for children with severe emotional disturbances. EPSDT could provide a complete framework for the early identification of young children with psychiatric risk factors and would

Telegram: @medical_k

www.konkur.in

support the effective targeting of comprehensive mental health and parenting services in the primary care setting of the family's "medical home."

COMMUNITY PSYCHIATRY AND THE PUBLIC SECTOR

Psychiatry's relationship to public sector agencies has, with some specific exceptions, been one of detachment because of the dominance of the private practice models before the advent of managed care and also largely because of the nature and structure of U.S. social welfare programs. Many psychiatry training programs lack meaningful rotations in public sector settings. In contrast to most industrialized nations in which comprehensive social welfare reforms were integrated, U.S. social welfare programs grew incrementally and categorically, that is, one category of service at a time. Large-scale initiatives, such as President Johnson's War on Poverty, have been implemented in a piecemeal fashion by fragmented federal, state, and local government bureaucracies. Various social service agencies have been created through a process and set of alliances that has been called the iron triangle. Advocates form an organization to champion a particular cause, such as blindness, developmental disabilities, primary care, or mental health, among others. They find key legislative sponsors who advance the cause through legislation and appropriation. This creates a bureaucracy, and then bureaucrats join the alliance. Through successive legislative sessions, the alliance of advocates, lawmakers, and bureaucrats builds a stronger categorical agency; for example, adults and families with dependent children or people with biologically based, SMI. From the 1930s through the end of the 20th century, U.S. social welfare agencies were created on this pattern: The system has resulted in generous funding and hopeless fragmentation of effort at local service delivery levels in which each agency depends on separate funding silos that also deliver conflicting rules and regulations.

It has been said that "mental health is not a place." Psychiatrists have a role at the receiving end of every categorical silo because the clients of each categorical agency experience mental illness or various addictions. Services for children with severe emotional, mental, or behavioral disturbances are a dramatic case of the importance of psychiatrists taking a leadership role in promoting comprehensive rather than fragmented services. Five categorical agencies—child welfare, education, primary health, substance abuse, and juvenile justice—all have a responsibility to care for these children. Especially for the children with the most severe disabilities, protective services, special education, the juvenile probation officer, and the child's pediatrician all need the consultation and support of a skilled psychiatrist. The situation is similar for adults with SMI, for whom case managers, vocational rehabilitation counselors, basic needs benefits specialists, social workers, psychotherapists, substance abuse counselors, parole or probation officers, legal conservators, visiting nurses, peer specialists, and physicians all may be mandated to deliver services. The need for psychiatric leadership is

Telegram: @medical_k

www.konkur.in

equally important for those who care for persons with mental retardation or developmental disabilities, for the older adult, for persons in vocational rehabilitation programs, and for persons in correctional programs. Virtually all public resources come through this complex of categorical agencies.

Health policy is formulated between government and employer purchasers and expressed unevenly through public health functions in communities, consumers, and advocates. Academic psychiatry bears responsibility for research, training, education, and workforce development for a behavioral health system that is only loosely integrated into the health care system. It will be impossible to achieve the ideals of the public health perspective on public and community psychiatry unless ways are deliberately devised to engage committed and proficient psychiatrists in meaningful roles in the operations of these agencies. Again, the factors at play in health care reform provide an opportunity to integrate the efforts of the complex and fragmented array of health and social service agencies by an emphasis on the primacy of the clinical process (maintained within the PCMH), the revision of funding mechanisms to encourage clinical sponsorship by accountable clinical entities, and emphasis upon the implementation of evidence-based practice standards.

BARRIERS TO ACCESS

The National Comorbidity Survey replication reports that less than 40% of those with severe psychiatric disorders have had an encounter with a psychiatrist in the last year; that one in six (15%) has received minimally adequate care; that one in twenty persons with substance use disorders received care. Even when mental illness is identified, people with socioeconomic adversities often do not, or cannot, get adequate mental health services in their communities. For example, although it is estimated that more than a quarter of a million incarcerated adults in the United States have psychiatric disorders, few were detected or received treatment until they reached jail or prison. Federal and state correctional systems have instituted mental health screening and treatment programs to address psychiatric disorders as a health problem for incarcerated adults and to manage the problematic behavior that can occur in controlled settings as a result of mental illness. On returning to the community, the vast majority of prisoners with psychiatric disorders cease to receive more than minimal mental health services: A recent study found that fewer than one in six (16%—strikingly similar to the National Comorbidity Study finding) received steady mental health services, and only one in twenty with addictions received steady substance abuse recovery services. Thus, access to mental health and addiction treatment services is far better in prison than in the community. This obviously causes great concern because of the possibility that correctional facilities may be a de facto system of care for low-income people (often of minority backgrounds) with serious mental illness.

Telegram: @medical_k

www.konkur.in

Evidence of serious and pervasive barriers to accessing mental health care can be found in several kinds of crisis situations. Children and adults in poverty increasingly are deferring physical and mental health care until illnesses become chronic and severe and then find it difficult to gain entry into any setting for services except public hospital emergency departments. Children with severe psychiatric or behavioral disorders are often held in emergency department facilities for days and even weeks because the staff cannot locate any treatment facilities with an appropriate level of care that have an opening or are willing to take the child as a patient (or to accept the child or family's insurance coverage or lack thereof). People who must rely on the public sector services thus face daunting obstacles when seeking appropriate mental health care because of the serious underfunding of practitioners and programs. The economic forces and public policy dilemmas that drive the ever-increasing cost of health care bear directly on public sector psychiatry, as well as on the lives of tens or hundreds of thousands of people who do not receive adequate care.

COMMUNITY PSYCHIATRY AND RECOVERY

It is important to survey where and how Public and Community Psychiatry will participate in the changes that are afoot for American health care and how it will pioneer and support recovery for vulnerable patients. The state hospitals were the first publicly funded health care, but they were separated in a strange way from the rest of health care as American medicine found its scientific legs in the reforms sparked by the Flexner Report in 1910. The strides that were made by medicine and science in the early 20th century were not possible for psychiatry because the tools were not yet available for the science of the brain. Psychiatry remained in the state hospitals with patients supported with public funds, and the separation between psychiatry and the rest of medicine widened. By the end of the century, this had changed dramatically, and psychiatry was building on a flourishing base of science. The change was advanced in the middle of the century when biologic psychiatry and the new medications began to be used and understood. But the hospitals were still operating, and the strange separation of psychiatry from the rest of medicine persisted. The former Commissioner of Mental Health in Massachusetts and Director of the NIMH's Joint Commission on Mental Health and Illness (1961), Jack Ewalt, MD, who had played a key role in the development of community mental health, wrote a small book that methodically detailed the operational decline of the state hospitals at the same time that the Hill-Burton legislation was funding sparkling new general hospitals in communities throughout the country.

The term Public and Community Psychiatry may change just as dramatically in the next decade as it serves more people and has access to newer medications but also the advantage of technology, wearables, and personalized medicine. The junction we are currently experiencing is that of aiming for remission or recovery.

ATTITUDES TOWARD COMMUNITY PSYCHIATRY

The premise of community psychiatry is to move care from institutions to the community. Thus, a direct correlate is to place clinics and other community resources in neighborhoods. An ideal scenario is full community acceptance and support of its most vulnerable individuals, but in fact, community psychiatry could face opposition from some neighborhoods; in this case, the opposition is linked to negative attitudes such as stigma toward mental illness, fear that community clinics would bring down the value of the neighborhood or bring about crime or violence, etc. Questionnaires such as the Community Attitude toward Mentally Ill questionnaire (CAMI) are designed to measure these attitudes and help guide public policy. Attitudes toward mental illness and community psychiatry can be viewed as individual versus societal. Different influences impact these two currents. Societal stigma links to systemic barriers, which are meant to be fought by community psychiatry establishments and systems. Individual stigma and discrimination are but one level of systemic stigma.

Overall, most people have neutral to positive attitudes to the idea of community psychiatry when it does not affect their lives unless they believe mental illness is associated with crime and violence. Increasing acceptability of community psychiatry would benefit from focused messaging and from starting mental services in a stepwise fashion. An important factor in increasing acceptability is also to increase individuals' direct contact with those who suffer from mental illnesses, as this step, increasing familiarity, has been found to help the acceptability of services.

As with other new concepts, the personality traits of recipients shape their responses on an individual level (for instance, using a big five-factor model, openness and agreeableness are associated with more acceptability and positive attitudes toward community psychiatry, whereas neuroticism is associated with less). Negative attitudes toward mental illness itself, such as believing that an individual with mental illness should be avoided and that marrying or partnering with someone with a mental illness is a bad decision (CAMI items), correlate with negative attitudes toward psychiatry, help-seeking, and community psychiatry perceptions. These opinions may be more negative in rural areas and in less industrialized countries.

Negative attitudes toward community psychiatry denote a poor understanding of the role and scope of the discipline. The advantage of having community services embedded in neighborhoods is to have accessible services bypassing access barriers and avoiding disconnecting the patient from their sources of support, typically families. Espousing negative attitudes to help-seeking and to community services easily leads to delay in care, presenting with more severe symptoms, and therefore reinforcing the view that mental illness is incompatible with normal everyday life. Of note, attitudinal barriers affect referral in mild to moderate cases, whereas structural barriers seem to be much more influential in severe cases,

Telegram: @medical_k

www.konkur.in

according to a WHO survey of 63,678 individuals with mental illness. As individuals with severe illness are the main recipients of community psychiatry services, it is essential that systemic and structural barriers be addressed, including societal ones.

A meta-analysis of studies on attitudes and perceptions toward mental illness shows an increasing trend toward better mental health literacy, moving toward a more biologic model of mental illness and perhaps greater acceptance of biologic, psychotropic treatments in middle- and high-income countries, but no significant change in stigma or attitudes toward mentally ill individuals.

Interventions to reduce stigma range from mental health education or provision of information, direct contact (shown to disconfirm stereotypes related to mental illness), indirect contact (increase familiarity), entertainment, and art (to replace stereotypes with healthier, more balanced views and more objective information), psychoeducation and even psychotherapy. In a review of more than 8,000 studies, Thornicroft et al. found that contact (direct) produces short- to medium-term knowledge improvement, but attitudinal improvement or does not occur. The impact of these attitudinal, stigma, and discrimination-based views can be far-reaching and affect funding and expansion of community resources, not just utilization. This area is not well researched and could benefit from manualization and increased fidelity in intervention delivery. Additionally, different campaigns could be needed for different types of mental illness and for low-, middle-, and high-income countries.

Attitudes of police officers are integral to community psychiatry response. For example, in an examination of how different agencies respond to borderline personality disorder patients, reviewers found that different agencies will assign different diagnoses to the same patient and hence deal with them differently, assigning them to different workflows. This illustrates the tremendous need to coordinate care frequently and across disciplines and institutions for successful community psychiatry outcomes.

Stigma and discrimination in community psychiatry also show in how police officers deal with mental illness, reflective societal prevailing attitudes. A common example is the use of restraints (handcuffs) when transporting patients from community settings to the emergency center or the hospital, even when the patient is voluntary.

COMMUNITY PSYCHIATRY AND PSYCHIATRIC TRAINING

According to the National Survey of Psychiatric Practice, more early and mid-career psychiatrists were working in the public sector/community psychiatry than in private settings, an increasing trend since the 1990s, with 2002 being the first year for more psychiatrists being in the former. In 1957, only 1,700 of the 10,000 American Psychiatric Association members worked in state hospitals. Within less than 20 years, the overwhelming majority of psychiatrists in the United States went

Telegram: @medical_k

www.konkur.in

from working in state hospitals to working in other settings that had little or no interface with the populations having an SMI or serious and persistent mental illness or with children with serious emotional disorders.

Training experiences in community psychiatry are required by the Accreditation Council for Graduate Medical Education. The swath of psychiatric care covered by community psychiatry has grown, and more psychiatrists practice in community-funded settings than in private practice or academic and research settings. Community psychiatry training tracks remain few and far between, with only four tracks being active in the United States in 2014. Creating alternatives to community psychiatry exposure in residency has relied on experiences with ACT teams or integrated psychiatry, though these two settings do not offer the same experience but rather some similarities. Community psychiatry fellowships focus on integrating care with shelters and primary care physicians to cover the spectrum of care the SMI population requires; the experience also focuses on building a human appreciation of the community psychiatry patient, an often traumatized individual dealt heavy blows by life. Despite all these limitations, there are views in favor of incorporating more community psychiatry experiences in psychiatry rotations, given the expansion of the field and the remarkable diversity of skills and collaboration opportunities it teaches.

What Skills Ought to Be Taught in Community Psychiatry Experiences?

The first is to improve knowledge of what to expect in the community psychiatry population, which has a particular profile of illness, as described in the SMI section. Patients in community clinics may often have complex trauma and overlapping symptoms, for which careful history taking is required. Familiarity with disease comorbidities is essential as most community psychiatry patients will suffer from co-occurring disorders. A common finding is that patients with psychotic symptoms of any nature will be labeled with a diagnosis of a primary psychotic disorder, such as schizophrenia or schizoaffective disorder, even when a proper diagnosis is a stressor or trauma-related disorder, or a substance-induced disorder. This label has implications for treatment recommendations and the adverse effect burden one may get from prolonged exposure to antipsychotics. Additionally, the stigma of having a psychotic disorder may cause detrimental long-term effects for self-image, hopes of recovery, and employment-seeking. More importantly, a mistaken diagnosis can lead to missed treatment opportunities, for example, focusing on pharmacologic measures and not referring to psychotherapy for trauma or giving antipsychotic medication but not an antidepressant.

The second skill essential to success in community psychiatry practice is efficient time management. As time is limited in most encounters, it is easy to skip elements of the interview that can be very revealing. Many learners are tempted to skip a formal mental status exam, recall testing, or to ask about first-rank psychotic symptoms, preferring to ask about hallucinations only. While time constraints are

Telegram: @medical_k

www.konkur.in

very real, the adequacy of history-taking remains the cornerstone of diagnostic delivery, and learning this skill is essential.

The adequacy of cognitive testing and of carefully surveying a prior history of violence and traumatic brain injuries has to also be emphasized. Individuals with SMI are at a higher likelihood to be victims of domestic and sexual violence, and individuals who have a family representative as a payee for their benefits (e.g., social security disability) are also noted to have a higher risk of family violence and victimization. Individuals who are homeless have a higher risk of traumatic brain injury compared to the general population. When rushing through a complex plan of care, often including off-label medication usage, the combination of head injuries, interpersonal violence, and untreated neuropsychiatric sequelae of these issues can largely contribute to poor understanding of instructions and poor follow-through. The same pattern can be found in patients with a history of heavy alcohol use. Thus, it is really important for learners to know how to complete thorough data gathering and select the types of cognitive tests, albeit brief, they will need to construct a proper formulation of the patient's level of impairment.

Third, the essence of community psychiatry is an ability to absorb complex situations and histories and to work through them in teams. Learners need to practice interprofessional data gathering, sharing, and decision-making. The physician's role in the community psychiatry team is pivotal but may be somewhat underemphasized. Learners will often find other team members thankful for a collaboration and for a nuances biopsychosocial formulation with proper use of terminology to accompany what they have already observed in their clinical interactions.

Fourth, the cultural aspects of community psychiatry, including engagement, understanding of the patients' background, and respect of cultural beliefs, have to be taught. There may be, in some subpopulations, a high preponderance of issues such as war violence, a refugee experience, or human trafficking that learners may not be familiar with.

Last, the structure of busy clinics in community settings, away from academic support and supervision, takes adjustment and modification of workflow. It is not studied whether the rates of burnout differ for community versus noncommunity psychiatrists, but the volume and severity of psychopathology seen in community psychiatry necessitate healthy coping mechanisms and often involves introspective reflection on severe illness and social justice.

TELEPSYCHIATRY IN THE COMMUNITY

The advent of telepsychiatry has the potential to improve delivery to community psychiatry patients but also highlights disparities in internet access and the ability to benefit from virtual psychiatry experience. In community psychiatry, financial restrictions have made encounters with psychiatrists shorter than they had traditionally been. There has been a shift toward more biologic aspects of

Telegram: @medical_k

www.konkur.in

psychiatric treatments and a dissociation of therapy and medication management sessions. So the baseline, typical visit in a community psychiatry setting has been described as brief and focused. These changes have been consolidated since the managed care movement in the 1980s.

Adept community psychiatrists maximize the use of the limited time they spend with patients and maximize engagement in those encounters. Using virtual encounters, however, has been challenging for the patient population typically served in community psychiatry settings. To achieve a proper result in a physician–patient encounter, aspects of rapport-building, diagnosis, and treatment decisions must be maintained; and to do so, the level of immersion in the visit, the level of engagement/emotional distance, and privacy have to be managed. The physical elements of the encounter, referred to by the psychoanalyst and artist Milner as the "frame," shift from in-person to virtual, playing the responsibility of privacy and adequate space to conduct the visit, and placing the onus of working out technical requirements and difficulty on the patient. Patients who do not have an adequate space to conduct the visit because of homelessness and lack of privacy in crowded living situations that many patients served in community psychiatry endure. This obstacle can translate into discomfort about discussing issues pertaining to the visit and potentially, because of increased sensory input, distractibility during the visit.

By and large, telepsychiatry is highly accepted, with some studies indicating that show rates in clinical settings improve with the use of virtual visits, as transportation barriers are bypassed and it is overall easier for patients. But it is not the case for individuals with SMI such as schizophrenia. Levels of engagement in therapy services and continuation of therapy use virtually may suffer as well in the SMI patient population. This fits with already known data from the Results From the National Comorbidity Survey Replication showing that by and large, individuals with significant mental illness remain under or untreated, especially in traditionally underserved groups, including older adult persons, racial–ethnic minorities, those with low incomes, those without insurance, and residents of rural areas, and therefore the patient populations that is the main target of community psychiatry. This is also the population hypothesized to not be able to fully utilize virtual visits. To engage in telepsychiatry, one has to have access to the platform needed and learn how to use the technology involved. The SMI population often has trouble with both, though once SMI patients are converted to telepsychiatry, they often remain and show equivalent levels of satisfaction to non-SMI patients. Thus, the difficulty may be to establish proper structural elements to help this transition. Of note, even though internet-enabled smartphone ownership is almost ubiquitous, patients with SMI in general, and psychosis in particular, hover around 78% in use, with even less owning a smartphone currently, and these parameters correlate with negative symptoms and cognitive functioning.

The Study to Promote Innovation in Rural Integrated Telepsychiatry (SPIRIT) study, currently underway in 12 FQHC in three states, aims to examine how to

Telegram: @medical_k

www.konkur.in

optimize engagement in care in patients with bipolar disorder or PTSD in a sequential, multiple assignments, randomized Trial design, and which of these patients would benefit from Telepsychiatry Collaborative Care. Preliminary data show that engagement in psychiatric care improved outcomes, but that success hinged on the presence of case management and psychology services in conjunction with telepsychiatry services; further, the telepsychiatry aspect is supplemented by an in-person case manager to facilitate adherence and implementation of treatment recommendations virtually given.

Virtual psychiatry applications for SMI can also clash with the nature of the disease targeted during the visit. The presence of delusions, such as mind-reading or persecutory delusions, belief of having an implanted chip or tracking device, could impair engagement with the psychiatrist on screen and potentially worsen the pre-existing delusion. Hallucinations would make engagement difficult as well and may be harder to redirect on screen compared to in-person interactions. Poorly controlled mood or personality symptoms, with acting out on screen (self-harm, using substances) is harder to mitigate virtually than in person as well. Potential negative outcomes of poor engagement could show as nonadherence with a treatment plan, dropping out of treatment altogether, and having to receive emergency or inpatient services because of clinical decompensation.

The addition of cultural and language barriers may further impair the successful use of telepsychiatry in non-English speaking patients. The Cultural and Linguistic Appropriate Services, via the U.S. Health and Human Services Department, outlines 15 standards of culturally competent care that have to be intermeshed with telepsychiatry structures and equipment and the ACGME framework. There are gaps in knowledge relating to applications of telepsychiatry to cultural aspects of community psychiatry. There are also severe gaps in determining the ideal clinical workflows to reliably help transitional the patients in community psychiatry clinics to virtual platforms successfully. It is likely that structural/organizational efforts have to be set in place for this purpose, including staff help to train patients on technology use, connect them prior to physician visits, and carefully review discharge instructions. These measures would help avoid further decreasing physician time and would solidify understanding of treatment recommendations. Special considerations should be paid to patients with substance use disorders needing regular drug testing, patients who receive long-acting injectable medications, and patients on medication regimens needing regular lab work monitoring.

ASSETS AND ADVANTAGES OF ONGOING PROGRAMS

The Harris County Experience

Houston, Texas, is the fourth largest city in the United States. Harris County, the third-largest county in the United States, has two networks of community psychiatry that work in a complementary fashion. One is a state-funded mental

Telegram: @medical_k

www.konkur.in

health system targeting the three main SMI categories (psychotic disorders, major depressive disorders, and bipolar disorders) and intellectual disabilities and strictly adhering to financial restrictions, thus serving the most vulnerable population in the county. Funded by the legislature, it follows all the above rules and provides an invaluable safety net to the community but providing outpatient services, a comprehensive psychiatric emergency program, and case management, and a crisis outreach service.

The second service, The Harris County Community Behavioral Health Program (CBHP), funded by the county itself, has had to grow and fill the gaps that state legislation does not cover. In doing so, an alternative model of providing community psychiatry services has evolved. In 2004, CBHP placed behavioral health staff, therapists and psychiatrists, into 21 community health centers in order to better meet the behavioral health and primary care needs of the uninsured county population, winning the 2007 American Psychiatric Association Achievement Award in the category of community-based programs. The program proved to be cost-effective, highly rated by specialists and primary care alike, and well-liked by patients who appreciated direct access to psychiatric services. As CBHP has continued to grow, options for specialized programs have emerged. Lessons from CBHP include the following:

- Direct access to psychiatrists works well for most patients, avoiding care delays and allowing quick treatment initiation and improvement.
- The absence of restrictions on diagnosis does not place a heavy burden on volume as initially feared. Past the first stabilization period, numbers have been manageable. Lack of diagnostic restrictions means that psychiatrists can do a proper diagnostic job and not feel compelled to add a diagnosis so the patient can qualify for services.
- Colocation with primary care and specialty medical services works well for patients who often have comorbid disorders. As discussed above, patients with SMI tend to be medically complex. Careful care coordination is often required for medication regimens, as antipsychotics while bringing benefits, may also worsen chronic medical issues.
- Substance use treatments are a must given the large percentage of patients who have SUD.
- Psychotherapy, both individual and group, are necessary for successful outcomes in community psychiatry given the high prevalence of traumatic experiences in this population.
- Culturally competent psychiatry is essential given the diverse makeup of our population.
- Colocation with other services offers opportunities to educate and provide informal support to colleagues, fostering collaborations.
- Multidisciplinary efforts allow better ability to screen for domestic violence, intimate partner violence, and human trafficking.

Telegram: @medical_k

www.konkur.in

- Community psychiatry is very local in flavor. Every clinic has a particular population, certain diagnoses that predominate, or an ethnic or racial group. The microcosm of a clinic is often difficult to describe, but psychiatrists embedded in each one usually have a feel for the needs and characteristics of their specific subpopulations.

The positive growth of CBHP has paved the way for more specialty programs that have emerged to fill the needs of the community, based on careful gap analysis and a desire to truly and decisively improve the lives of our patients. Specialty programs include the follow.

Multi-Visit Patient Program (MVP)

As discussed above, the goal of a successful community psychiatry experience is the smooth transition of patients from inpatient acute hospitalizations when needed to outpatient care. This lofty goal is not always possible, and the literature is rife with descriptions of patients who often present to emergency services. These patients are often substance users but sometimes have psychosis, mood, or personality disorders. Derogatory terms such as frequent flyers were much used in the 1980s and were gradually replaced by more neutral terms such as MVP. The MVP program provides linkage of patients who have more than six emergency center visits per year to rehabilitation resources, housing resources, and other community resources as indicated. The main drivers of utilization seem to be divided into behavioral, social, and medical. Solving these issues is often not within the hands of the medical system or the psychiatrists, testifying to the interdependence of agencies on each other in the community psychiatry structure. The MVP program has been successful in mitigating recidivism for multiple individuals, much to the relief of staff and patients alike.

Maternal Perinatal Addiction Treatment Clinic

Based on the Maternal Opioid Misuse model (MOM) funded by Medicaid, the MPAT clinic aims to serve the needs of pregnant women with histories of drug use. Women who use drugs have a much higher chance of unanticipated pregnancy, shorter durations between pregnancies than recommended by the WHO for optimal health, and frequent negative outcomes in relation to domestic violence and intimate partner violence. Pregnant women will often try to stop drug use when they discover they are with a child, but often fail: women who are pregnant tend to use less compared to those who are not, use tends to decrease over the trimesters, but often quickly rebounds postpartum. They report feeling judged and embarrassed, not just because of substance use but also because of associated behaviors such as prostitution. The percentage of pregnant women who use illicit substances (drugs, alcohol, tobacco) is 20.8%, according to National Survey on Drug Use and Health, from SAMHSA. Beyond just numbers, substance use disorders have been gaining press as state after state (UT, CO) highlighted

Telegram: @medical_k

www.konkur.in

concerns about the significant contribution of SUD to maternal mortality. The Maternal Mortality and Morbidity Task Force and Department of State Health Services, in its 2018 Biennial report, recommends the following:

- ensure that women with substance use disorders and mental health conditions have insurance coverage for necessary care services;
- support models of maternal health care that integrate behavioral health services; and
- develop strategies to ensure that behavioral health and community services to support long-term disease management are readily available, including expanding the number of behavioral health care providers and services across the state.

Thus, there was clearly a need for a specific intervention. The group of women targeted for this intervention are frequently victims of the intersectionality of trauma, poor social determinants of health, risky practices, like substance use, and high-risk medical pregnancies, in addition to potential other medical conditions. The MPAT clinic provides multidisciplinary support from neonatology, anesthesia, addiction, and general psychiatry, psychology, social work, maternal–fetal medicine, and from social and community works in inpatient treatment centers. The program has linkage to substance treatment centers, the jail system, the child and family protective systems and is involved in outreach efforts. Since its inception, the program has seen a tremendous increase in the number of referrals, and has been able to implement Universal Substance Use Screening in all county clinics, as screening is found to be superior to urine drug testing, is not confounded by bias and false positives, and gives the opportunity to intervene during the screening. Substance use is likely underrecognized without screening, and the MPAT program is an example of an evidence-based, multidisciplinary intervention that is unique to community psychiatry.

THE LARGER PICTURE

Community psychiatry has the opportunity to shape perceptions of mental illness and fight stigma as its reach increases. By interacting with multidisciplinary teams and working on social determinants of health, it is possible to generate a positive, evidence-based picture of appropriate, successful treatments. To achieve success, community psychiatry has to tackle societal issues affecting its patients, including gun violence, homelessness, the role of the legal system, and the limitations of psychotropic medications. As discussed above, the groups of patients served by community psychiatrists no longer just represent the sickest individuals with SMI. Therefore, community psychiatry must become flexible and integrate treatment for co-occurring disorders and personality pathology. It also has to include health promotion and accommodate insurance system payments.

Telegram: @medical_k

www.konkur.in

A little-discussed aspect of community psychiatry is the fact that it is the de facto safety net for chronic childhood disorders and intellectual disabilities but also deals with emergency center recidivism, inpatient hospitalization recidivism, etc. The next decade will see specific subspecialties burgeoning within community psychiatry. The examples of programs illustrated above give an idea of the growing scope of community psychiatry and the potential it has. Community psychiatry is not the same it was 10 years ago. Patients who are employed, but want ease of access and someone with the ability to handle difficult cases, may be the next community psychiatry beneficiary, and services will have to be flexible to accommodate those needs.

56.2 Reforming Health Care

NIDAL MOUKADDAM, M.D., PH.D., AND ASIM A. SHAH, M.D.

Telegram: @medical_k

www.konkur.in

Reform is the process by which one achieves health and optimal utilization of health resources. Health care is provided in public versus private sectors, with the balance differencing by country and sociopolitical agenda of governing political parties. Yet the realities of care provisions are also heavily impacted by a country's financial resources and organizational capacities and broader geopolitical forces such as conflicts/wars and natural disasters. Thus, health care delivery, and therefore health reform, has to include a somewhat stable/static, long-term planning element and more dynamic adaptive capacity reflecting budgetary and sociopolitical realities.

Health care delivery occurs in acute, primary, secondary, tertiary, and community-based services. When thinking of reform, different strategies and goals apply to each setting, with the overarching goal of maintaining an efficient, nimble, and cost-effective health care continuum.

In the United States, the goals of reforming health care are

- improving the experience of care
- improving the health of populations
- reducing per capita costs of health care.

Another way to consider reform is to think of it as

- insurance market reform
- delivery reform
- payment reform.

One would also be remiss not to mention that the pandemic will have long-lasting impacts on reimbursement and medical models. A central theme of reform, to be conducted successfully, is to maintain the balance between innovation and collaboration and stability. Reform is inextricably linked to politics.

The COVID-19 pandemic has shown the perils of systems where health care coverage is not easily accessible and the financial needs of keeping a population healthy. This chapter will discuss how reform can gain from discrete, well-defined measures and how those measures interface with politics and the law. The interface of medical reform with legal issues can impact the environment in which physicians practice, via tort reform and change caps on economic and noneconomic damages, with improving availability of medical review panels.

Puzzling aspects of health care reform center around the simple fact that health care recipients are *individuals.* In contrast, the stakeholders range from patients, researchers, policymakers, and the general public at the receiving end of reform, even when in a healthy state. Health care delivery has economic, financial, logistical, and political dimensions and a public health and social scope. Health care delivery is typically a significant expense for a country.

The Commonwealth Fund report "Mirror Mirror: reflecting poorly" (https://doi.org/10.26099/01DV-H208) compares the health care systems of 11

Telegram: @medical_k

www.konkur.in

high-income countries by analyzing 71 performance measures across five domains—access to care, care process, administrative efficiency, equity, and health care outcomes. These are drawn from surveys and administrative data from the Organisation for Economic Co-operation and Development and the World Health Organization. Last published in 2021, the report still points to the United States as ranking last on access to care, administrative efficiency, equity, and health care outcomes, but second on care process measures. It is estimated that 16.8% of U.S. GDP is spent on health care.

In the United States, an individual who cannot afford private insurance, for example, from a job loss, applies for Medicaid if they meet socioeconomic criteria, apply for Medicare if they received social security income for at least 2 years, or buy insurance through the Affordable Care Act. The transition from personal experience to structural health coverage expansions is where the sociopolitical realities interfere. For the example listed in this paragraph, the options experienced by the individual rely on states expanding care coverage. This expansion can be done in multiple ways that reflect a country's, state, or community structure and political leanings. In the United States, previously suggested ways to ensure expanding coverage include expanding Medicare coverage to individuals starting the age 60 instead of 65, Medicare for all or other inclusive plans, or expanding Medicaid. The tenet of Medicare for all (or any name that one chooses to select for a reform campaign) would be controlling the prices paid to physicians, hospitals, and drug companies. This would theoretically be achieved by reducing administrative costs, including insurance overhead and profits. Thus, Medicare for All or equivalent plans could be the equivalent of quasi-universal coverage.

To put things in perspective, let us look at the dimensions from the Commonwealth Fund report, then compare them to the triple aim espoused by the ACA:

- **Access to care** includes measures of whether an individual can afford proper health care and if they can get this health care in a timely fashion. Affordability of health care is linked to timeliness because seeking emergency services will usually be linked to worse care outcomes and higher expenses. Countries that do well in that respect usually provide some sort of universal health care formula. While never without criticism, those universal access programs avoid desperate emergency service use as a last resort. This measure includes access to after-hours and weekend care and insurance denying payments of a claim or paying less than expected, therefore leading to financial issues for patients.
- **Care process** includes measures of preventive care, safe care, coordinated care, engagement, and patient preferences. This aspect has improved tremendously in the United States since the ACA and Patient-Centered Outcomes Research Institute (PCORI) initiatives were implemented. U.S.-specific challenges are cost-effectively maintaining care processes while minimizing care disparities. Additionally, the U.S. ranks lowest in terms of

Telegram: @medical_k

www.konkur.in

patients having continuity with the same doctor, which is a concerning measure for individuals, as continuity is associated with better long-term patient outcomes.

- **Administrative efficiency** refers to the bureaucratic processes by which health care provision is managed. Can a physician get their patient's medications or referrals efficiently or promptly? Can they implement required guidelines quickly when needed? In this measure, the U.S. ranks poorly compared to other wealthy countries, and most physicians rank administrative efficiency as suboptimal. Two aspects of administrative efficiency are subject to reform potentially. One is the administrative burden aspect and how much physicians have to do to schedule and implement treatment. The other is the administrative burden becoming a deterrent for patients to seek care. This links to patients getting more emergency care and further bloating and excess expenditures in the system.
- **Equity and Income-Related Disparities** is a well-known, well-advertised issue in the United States that remains at the forefront of the administrative and political agenda. The ACA implementation has helped bridge the gap, but as of the 2021 data, minorities in the United States still have subpar access to care and poorer health outcomes than their nonminority counterparts and those in other countries. One notable poor statistic in the United States is that maternal mortality is 17.4 deaths per 100,000 live births, whereas the next high-income country (France) has a rate of 7.6 per 100,000 live births.

President Nixon countered with an employer mandate plan; Physicians for National Health (PHN) proposed "single payer"		mandate, privately administered, plus Medicaid and Medicare; PNH plan financed by federal tax with single fund in each state	public assistance; failed to pass Nixon plan: Maintained public assistance; added social insurance; failed to pass PNH plan: Merged social insurance and welfare; failed to pass
1991–1994 Clinton Health Security Act: Opposed by insurance and pharmaceutical industries and small employers, single-payer advocates; proposed voluntary approaches	Comprehensive health care	Administered federally; financed through governmental funds, employer mandate, and individual mandate (with subsidies); voluntary: Tax incentives for employers; medical savings accounts (MSAs) for individuals	Model: Integrated social insurance and public assistance Failed to pass

From a mental health perspective, suicide rates in the United States have continued to rise for the past 20 years; and while U.S. patients are more likely to accept mental health care, they have less access to mental health professionals and social services. Almost a quarter of individuals in the U.S. report having been told they have anxiety, depression, or another mental issue, but the abundance in diagnosis is not accompanied by effective treatment or mitigation of adverse outcomes such as suicide (https://www.commonwealthfund.org/publications/issue-briefs/2020/may/mental-health-conditions-substance-use-comparing-us-other-countries).

HEALTH CARE REFORM IN THE 20TH CENTURY: A HISTORICAL OVERVIEW

Telegram: @medical_k

www.konkur.in

The reform of the U.S. health care system has been periodically and repeatedly proposed since and before the social reforms of President Franklin Roosevelt. Presidents Harry Truman, Jimmy Carter, Gerald Ford, George H. W. Bush, and Bill Clinton all considered and proposed reform plans. Earlier proposals for national health insurance set the framework for these proposals. Table 56.2–1 summarizes the significant periods of legislative activity since the early 20th century and the complex elements involved in the proposals. Earlier proposals coupled health with other social welfare programs; later proposals narrowed in on health care as health care costs increased dramatically in the later part of the 20th century. Proposals were designed on either the model of social insurance or that of public assistance or welfare. As the importance of universal coverage became clear, these models merged. The locus of administration or control of the proposed health insurance programs—by employers, the federal government, or the states—became important. In particular, the most critical issue was the financing of the system: through government funds, the requirement that employers pay for their employees ("employer mandate"), or the requirement that individuals buy their own insurance ("individual mandate").

In the last decade of the 20th century, as health care costs continued to spiral upward, the proposed Clinton Health Security Act generated a tremendous amount of energy but eventually failed to be enacted. Large employers changed their methods of purchasing care, hiring companies to introduce a variety of cost control techniques, generally described as "managed care." Meanwhile, "incremental" measures were taken in the 1996 Health Insurance Portability and Accountability Act, the 1997 Balanced Budget Act, which limited payments to hospitals, and the 2003 Medicare Prescription Drug Improvement and Modernization Act. In addition to providing partial coverage to Medicare enrollees for medications, the latter act provided the Medicare program with the flexibility to introduce more aggressive health care purchasing techniques to control cost. These measures also supported individual incentives to control cost through new insurance models such as medical savings accounts, which combine tax-exempt personal savings for health care with catastrophic insurance coverage. The movement toward "managed care" purchasing did slow the rising costs for a few years, but its requirements were relaxed due to a strong reaction against control by both patients and providers.

Managed Care: A Phenomenon on the Path to Health Care Reform

The freewheeling spirit resulting from having generous public and private financial support for health care from roughly 1950 to 1980 led to a heady time for U.S. medicine. Society supported the clinical advances built on research that promised breakthroughs just over the horizon. Practitioners were, by association, part of this new era, and, as authorities in their professions, their determination of what patients needed was funded almost without question by public and private sources. As resources became limited owing to many factors, such as inflationary pressures

Telegram: @medical_k

www.konkur.in

and legislation, payers began to question what it was that health care was delivering for the dollar; that is, the issue of value was raised for the first time in the health economic equation by those paying for health care. A corollary of the issue of value was the question of the accountability of practitioners. Subsequent landmark studies demonstrated geographically differing practice patterns and consequently different costs but similar outcomes for the same disorder or disease. This raised the general question of why this should be the case? Other fundamental issues that have emerged include the following: How can access to care be broadened? How can clinical outcomes as a result of health care be improved? What about the uninsured? How can costs be controlled?

Utilization Review

Employers and purchasers embraced the concepts of utilization review and utilization management as strategies to try to ensure that the most appropriate and most cost-effective clinical decisions with the best outcomes were being made on behalf of any given patient. For this discussion, utilization management is considered the global concept that subsumes various aspects of the review process. These days, virtually all care, except for the increasingly rare full fee for service, is under some form of review and management process, whether public or commercial payer.

Some practitioners consider the review process an intrusion into the clinician–patient relationship. The process can be cumbersome, and disagreement about the decisions reached during a review often contributes to resentment. With some justification, practitioners are irked because third parties with no clinical relationship to the patient have the authority to influence the process of care, challenging the practitioners' clinical autonomy. At one point, the clinical criteria used in the review process were considered "proprietary" and not available to clinicians, so they might see how their care process was being reviewed. At the same time, if practices were reasonably standardized and if practitioners had training (or retraining) that was uniform with a focus on (1) diagnostic accuracy, (2) evidence-based, cost-effective practice, and (3) attention to clinical outcomes, perhaps a great deal of the variance seen in practice might diminish, thereby reducing the need for third-party reviews.

Selective Closed Panels and Networks

Another strategy to improve care while reducing costs was to create selective or preferred provider networks in which clinicians applied to become members of the clinical panel of a managed care organization. By applying to be a network provider, clinicians agreed to practice within the guidelines established by the managed care organization. In theory, the network had some degree of compliance and fidelity to the standards of practice of that particular managed care company. However, this was more of an idealized system of care for several reasons. In

Telegram: @medical_k

www.konkur.in

many parts of the country, the clinical marketplace is highly competitive because of a glut of practitioners vying for limited clinical dollars. Functionally, this means that many individual practitioners may apply to a particular managed care panel because of simple economics (i.e., they need the income) rather than an interest or willingness to practice within a managed care framework. So, there may be little selectivity about a particular panel of providers because the process is more open-ended until the managed care organization has determined there are sufficient providers for a given geographical area. Whether justified or not, some managed care organizations have reputations for being difficult to work with, reimbursing at what is viewed as “low rates.” As a result, such organizations may have difficulty attracting sufficient providers and may be less selective than is preferable. In more affluent areas, some practitioners, especially well-established ones, do not accept insurance of any kind, so utilization review is not part of the overview of their patients’ clinical care.

Care Management and Intensive Case Management

Much psychiatric care is done with persons with chronic mental health conditions. Driven mainly by the demographic realities of an aging population, health reform considerations focus on chronic illness care and the concept of care management and intensive case management, virtually identical concepts. By analyzing the process of care for various disease entities, care management attempts to introduce discrete improvement steps to improve the efficiency and coordination of care, enhance patient compliance, achieve better outcomes, and reduce costs. Care management has been used with chronic illnesses, such as diabetes or hypertension. In psychiatry, care management has been successfully applied to mood and anxiety disorders. However, the high degree of practice variability not only by the provider but also by a geographic section of the country reflects the historic inability and failure of the health care system to incorporate readily and to standardize quality improvement and evidence-based ideas into the system in which clinician, patient, and health system engage.

Managed Behavioral Health Care

In the late 20th century, costs for psychiatric and substance-abuse services rose considerably faster than the costs for physical health care. The effort to instill accountability among practitioners, expect value for payment, improve access, provide cost-effective services, and use to the extent possible evidence-based approaches to treatment to improve outcomes created a backlash by mental health practitioners against managed care. Scandals in the 1980s and 1990s of for-profit managed behavioral health care companies engaging in unethical practices overshadowed the equally scandalous accounts of practitioner excesses of use and inappropriate, often misguided, treatment. Managed behavioral health care became synonymous with denial of care and, in for-profit systems, the image of

Telegram: @medical_k

www.konkur.in

fat-cat corporate leaders with large salaries and generous stock options derived from the misfortune of patients and beleaguered practitioners, the latter mired in an endlessly confusing system of external review, was readily accepted by many as the only reality. What was missing in the tumult was the perspective that managed behavioral health care was a way station on the path to behavioral health care reform.

Public Sector Managed Behavioral Health Care

Governmental agencies purchase 60% of all behavioral health care at federal, state, and local levels. As resources followed patients out of the state hospitals, much of the state expenditures remained controlled by agencies responsible for specific populations such as mental health, criminal justice, child welfare, and social services. Medicaid, the entitlement program for those unable to afford health care, began in 1965 and is the primary funding source for local governments to pay for public behavioral health care services. Medicaid's overall costs rose dramatically by 2000, accounting for more than 15% of all U.S. health care costs, with behavioral health care accounting for about 10% of Medicaid spending.

Medicaid's behavioral health costs became a severe liability at the state or county government level because of yearly cost overruns. As a result, government agencies turned to managed care contracting of Medicaid services to shift risk to nonprofit behavioral health care provider organizations, thus limiting the state's liability.

State governments also soon learned that they could redirect the bulk of their behavioral health expenditures for severely disabled persons in the categorical agencies into the Medicaid program, thus increasing their match base for the Medicaid Federal Financial Participation (FFP) and leveraging federal revenues into their state general fund. Medicaid expenditures continued to increase, and this was a major contributing factor to the 100% increase in public mental health dollars from 1956 to 2003. The downside from the point of view of the seriously and persistently mentally ill was that the control of these services went from the public agencies responsible for behavioral health care to commercial managed care companies whose networks and capacities were more in tune with the needs of employed populations.

Safety-net hospitals, community mental health centers, and academic medical centers were under extreme financial distress and endured substantial service limitations. Thus, while public sector experiments with large-scale managed behavioral health care produced some successes, costs, and quality of care continued to be problematic.

Private Sector Managed Behavioral Health Care

Government deregulation of the hospital industry enabled the astronomical growth of for-profit mental health and substance abuse facilities, many organized as large

Telegram: @medical_k

www.konkur.in

hospital chains. As a result, the use of mental health and substance abuse treatment increased dramatically, exemplified by the fourfold increase in adolescent inpatient admissions between 1982 and 1987. The proliferation, financial success, and perceived abuses of proprietary psychiatric hospitals caused great consternation among employers, insurers, legislators, and the public. Many hospitals, including presumably less exploitative, not-for-profit hospitals, seemed to provide treatment based on reimbursement potential rather than actual medical necessity. One of the physician pioneers of the managed behavioral health care industry commented that it was a myth that substance abuse treatment required a fixed length (usually 28 days) of inpatient treatment. Rarely has such a fixed false belief had so little factual support or received such fervent adherence. As early as 1983, a report from the Office of Technology Assessment that the literature failed to demonstrate a general superiority of inpatient over alternative treatment settings, as measured by outcome. Subsequent studies have confirmed that hospital or residential treatment is neither necessary nor sufficient for most people with substance use disorders.

Nevertheless, long inpatient stays for adolescents with behavioral or substance abuse problems became common. Inappropriate hospitalizations for excessive periods became exposed as proprietary systems flourished. Health care payers (employers, insurance companies, Medicare, and Medicaid) became quite rightly concerned by the rising costs and the suspect practices. They questioned the actual medical necessity of costly services such as extended psychiatric inpatient stays. The psychiatric profession also successfully argued that inpatient stays for psychiatric patients could not be actuarially determined with any precision, thus making federal Medicare mental health inpatient criteria exempt from federally determined diagnostic-related groups (DRGs) for reimbursement purposes. In this climate, it became more and more challenging to maintain adequate oversight or regulation of mental health and substance abuse treatments. Private employers became the first to respond proactively to these concerns by contracting with the pioneer entrepreneurs of the first generation of managed behavioral health organizations (MBHOs) led by mental health professionals who had the credibility and specialized knowledge and skill to provide oversight of mental health and substance abuse practitioners.

This initial phase of managed behavioral health care (approximately 1983 to 1987) began with traditional indemnity insurers changing benefit designs in the hope of discouraging excess use. Tactics included limiting mental health coverage for specific disorders or treatments and instituting deductibles, copayments, and benefit maximums. These efforts were ultimately all unsuccessful. Entrepreneurial companies, led by psychiatrists and psychologists, began their entry into the health care marketplace through contracts with HMOs struggling to administer behavioral health care benefits. These initial efforts' dramatic success was driven by the limitation of access to mental health and substance abuse services. Access was limited through tight medical management (e.g., instituting strict medical necessity

Telegram: @medical_k

www.konkur.in

criteria for level-of-care determinations, limiting authorizations for inpatient admissions and continuation of stay, or the proliferation of denials of payment for care), as well as by restricting the network of caregivers and institutions credentialed to provide care for the population covered.

The first phase of limitation of access, aimed at restricting access for patients, was successful but led to dramatic customer complaints. As large employers (not HMOs) became the target for MBHO marketing, patient choice was increased by expanding provider networks, but overall costs were now saved through a dramatic reduction in rates paid to providers. Typical discounts were 20% to 25% of professional fees and 25% to 35% of hospital charges. These discounts seemed Draconian at the time and were widely seen as threats to behavioral health care providers' solvency, but more significant fee reductions were to come. This network expansion and reduction of provider rates characterized the second phase of the managed behavioral health care revolution (approximately 1993 to 1998).

The third phase (1998 to the present) has been termed the phase of industry consolidation. The proliferation and financial success of MBHOs in the 1980s and early 1990s led to the development of administrative models, information system infrastructure, extensive provider network management techniques, and sophisticated medical management strategies that resulted in significant economies of scale. Nevertheless, provider rates continued to fall, along with profit margins. Utilization patterns also changed dramatically. In tightly managed markets (such as Minneapolis and Los Angeles), the average commercial inpatient days per 1,000 members declined: from approximately 150 in 1983, 75 in 1990, and 10 to 15 in 2000. The cost to employers of behavioral health care under traditional indemnity plans was approximately $9 per member per month. By 2000, these costs fell dramatically to less than $3 per member per month. To sustain these reductions, the MBHO industry experienced dramatic consolidation. Within a few years, through mergers, acquisitions, and market growth, the industry became concentrated into a small number of very powerful behavioral health care corporations.

HEALTH CARE REFORM IN THE 21ST CENTURY

Whether admired or not, many of managed care's innovations are irreversible. Managed care's financial success was dramatic (i.e., decreased behavioral health care costs). Utilization management by managed care companies led to significant decreases in the average length of inpatient stays for psychiatric patients and fewer total inpatient days for populations of patients as a whole. Despite widespread complaints of diminished physician, hospital, and patient autonomy, constraints of decreased physician and hospital reimbursement, and anecdotal horror stories of sacrificed patient health care quality, there is no systematic way of convincing lawmakers that managed care destroyed the quality of the U.S. health care system and no easy way to reverse the changes that have happened to

Telegram: @medical_k

www.konkur.in

medical practice in general and psychiatric practice in particular. One could reasonably argue that the health care system was already imploding, which was the impetus for yet another effort at reforming the system. The National Committee on Quality Assurance (NCQA) points to significant improvements in health care quality resulting from efforts at self-improvement by the managed care industry when these are conducted properly. Managed care contributed to health care quality by emphasizing population-, evidence-, and guideline-based health care, chronic illness care management, and information technology to evaluate and change the process and outcomes of care.

However, by the beginning of the 21st century, health care costs continued to spiral upward in the United States, and health care quality remained substantially below standards set in other comparable affluent societies (see Table 56.2–2). With overall health care costs rising at more than twice the inflation rate, employer groups could not sustain the resultant increase in premiums.

Waste in Health Care

In recent years, considerable attention has been paid to eliminating waste in U.S. health care, not just redesigning a dysfunctional health care system with improved access, better quality, improved efficiency, expanded coverage to enhance equity, and lowered costs. It has been estimated that a third of the annual health care expenditure ($2.8 trillion in 2014) could be eliminated without any adverse health consequences to individual patients. Unnecessary administrative expenses, care that provides little or no value, costs associated with medical errors, and fraud are examples of waste. There have been six areas identified that are responsible for the waste:

Telegram: @medical_k

www.konkur.in

1. poor care delivery
2. poor care coordination
3. excessive care
4. excessive administration
5. pricing failures
6. fraud and abuse

These six areas were projected to push U.S. health care expenditures to 20% of the gross domestic product by 2020. Not surprisingly, therefore, in the first two decades of the 21st century, the urgency of health care reform has intensified as the growth of U.S. health care spending is projected to double in 8-year intervals representing almost 18% of the gross domestic product in 2011. The competitive position of the United States in the global economy is threatened, and many argue that the economy cannot be fixed until health care is fixed. Influential reports show that the United States spends considerably more on health care than any other country. This growth in spending consistently outstripped collective income. Yet the United States ranks poorly among industrialized countries in standard measures such as life expectancy and infant mortality. Moreover, it cannot provide health insurance to at least 15% of its population. Therefore, health care reform will remain at the forefront of the domestic agenda as long as the path of sustainability has not been achieved.

THE IMPACT OF THE AFFORDABLE CARE ACT (ACA) AND THE TRIPLE AIM DEFINITION—APPLICATIONS TO MENTAL HEALTH

"Between the health care we have and the care we could have lies not just a gap, but a chasm." IOM, 2001

The key provisions of the ACA are designed to:

- Provide coverage for more people
- Provide more benefits, better protection, and transparency
- Lower costs for consumers and government
- Provide quality and efficiency
- Provide a stronger workforce and health care infrastructure.
- Provide a greater focus on public health, prevention, and chronic illness care
- Support innovative techniques and technologies

Meeting the three inter-related concepts (1) improving the experience of care, (2) improving the health of populations, and (3) reducing per capita costs of health care is required to achieve high-value care as reform shifts from a *volume-based* to a *value-based* system. The passage of the ACA as law in 2010 laid the foundation for health care transformation. Key policy reports in the first decade of the 21st

Telegram: @medical_k

www.konkur.in

century sparked the need for the ACA, including the influential report of the Institute of Medicine (IOM), in 2001: “Crossing the Quality Chasm: A New Health System for the 21st Century.” The report highlighted the disparity between best practice and current practices in the United States and the effect on widespread variability and escalating health care costs. It established Six Aims for the 21st-century health care system, espoused by the ACA.

The larger health care systems in which psychiatrists and other behavioral health specialists work profoundly impact the delivery and outcomes of psychiatric and physical health care services. Internationally, and over the last two decades in the United States, the dominant theme in health care system reform shifted from an emphasis on managed care to a tripartite focus on patient-centered care (as a complement to provider-driven disease management), improvement of the health of entire populations with interventions tested in comparative effectiveness research (CER) (as opposed to individual-level observational or clinical trial research), and the development of incentives to maximize health care cost-effectiveness (as opposed to containing costs by restricting access to or reimbursement for health care). The Triple Aim has served as a foundation for health care reform, and we are now in a place to examine some of its effects a decade later (see Fig. 56.2–1).

The guiding principle of the Triple Aim is that health care quality should be defined based upon the vantage of the recipient, *the patient*, and not externally by technical or clinical considerations. Beginning with a patient-centered (as opposed to disease-based) perspective, health care must be teamed up with public health (i.e., prevention and health promotion) and social services to fully meet the needs of individuals and families and create a healthy overall population. This biopsychosocial approach integrates otherwise fragmented or missing services and makes primary (rather than specialty) health care the driver for delivering services—containing and reducing costs and promoting health. The implementation of this system has been arduous and carried its own challenges. The concepts of patient-centeredness and equity are not new or radical but have been recurrent themes in health care reform efforts in the United States for more than a century. They have been the bedrock and the foundation in the more successful health care systems in other affluent and industrialized countries internationally.

www.konkur.in

FIGURE 56.2–1. Design of a triple aim enterprise. (Institute for Healthcare Improvement. Design of a Triple Aim Enterprise. 2012. https://www.ihi.org/Engage/Initiatives/TripleAim/pages/default.aspx.)

For psychiatry, specifically, the impact of patient-centered care is far-reaching given the fact that individuals with serious mental illness (SMI) represent an undue large portion of underinsured or uninsured patients and have multiple co-occurring nonpsychiatric disorders, e.g., medical, addiction disorders, in addiction to negative social determinants of health.

Expanding the concept of best practice to include public health and prevention efforts and coupling this with chronic illness care management are among the key points of the IOM monograph and are aligned with ACA triple aim, as are the pivotal roles of preprofessional training the retraining of the existing workforce. With finite resources for health care amid competing priorities, the reformed health care system and, specifically, the reformed behavioral health care system must find ways to integrate effectively multiple factors, such as (1) practitioner, system, and patient accountability; (2) economic support for public health efforts, such as prevention and early identification; (3) the linkage of acute care with chronic illness care/collaborative care/coordinated care management; (4) improved access; (5) effective integration with primary and specialty care; (6) development of models of the most clinically effective and cost-effective care (e.g., integrated with public and physical health, interdisciplinary in practice, with continuity of care across venues); and (7) meaningful involvement of patients and, where feasible, their families, in the process of care. Managed care can be viewed as a sign and a symptom within the broader construct of health care reform. The creation of medical homes has been the *first step* toward this integration.

Numerous studies have shown the high prevalence of behavioral health conditions in physical health. Patients with comorbid illnesses (mental, substance

Telegram: @medical_k

www.konkur.in

use, and physical health disorders) represent the most costly group in health systems. Many of these individuals are seen in public sector systems, often incarcerated or homeless with inadequate physical and behavioral health care.

A dramatic example of the need to find ways to integrate primary care and behavioral health care in coherent delivery systems is the “dual eligibles,” that is, the Medicare and Medicaid eligible population. This group is among the most costly of any population of patients, not only because a large portion of the poor and very older adult patients are in long-term care (nursing homes and hospice), but also because those in the community find it difficult to negotiate consistent access to health care due to their disabilities. Typically, a given state might find that 40% of their dual-eligible population have serious and persistent mental illnesses.

Sadly, real obstacles remain in reforming health care related to mental health outcomes. The National Committee for Quality Assurance (NCQA) reported that despite essential strides made in the general medical and surgery sectors, there continued to be disturbing exceptions to overall health care quality improvement in mental health, that the situation remained poor and concerning with individuals afflicted with SMI dying 7 to 10 years earlier than their non-SMI counterparts. The IOM’s recommendations centered first on linking mental health and substance use treatment more closely with general medical care; second, the details of the original Quality Chasm report, its aims, rules, and redesign approaches, should be operationalized in the treatment of mental health and substance use disorders. Inadequate leadership and resources have been cited along with these areas having fewer objective, standardized diagnostic methods compared to physical health disorders; weakness of the evidence base for supporting quality measures; lack of coherent strategies for adopting quality measures that get back to the problems in leadership in assuming this responsibility to move the field along. *Fewer than 5% of the National Quality Forum’s list of 650 quality indicators relate to the care for individuals having mental health and substance use problems*.

The 2001 IOM Quality Chasm Report articulated a strategy for health care improvement in a separate report for mental and substance use disorders because it has numerous distinctive characteristics. These distinctive characteristics include the greater stigma associated with mental and substance use conditions, more frequent coercion of these patients into treatment, a less developed system for measuring quality and improvement, a more educationally heterogeneous workforce, the fragmentation of the behavioral health care system with inadequate communication and coordination of care among its components, and a perverse funding structure.

In its report “Improving the Quality of Health Care for Mental and Substance Use Conditions” (2006), the 10 items listed as guidelines/priorities for mental health and substance use conditions are as follows:

1. Care is based on continuous healing relationships.
2. Care is customized to patient needs and values.

Telegram: @medical_k

www.konkur.in

3. The patient is the source of control.
4. Knowledge is shared, and information flows freely.
5. Decision-making is evidence-based.
6. Safety is a system responsibility.
7. Transparency is necessary.
8. Needs are anticipated.
9. Waste is continuously decreased.
10. Cooperation among clinicians is essential

The report also noted the considerable societal and workplace burden that mental and substance use conditions bring with substantial employer costs from absenteeism, “presenteeism” (i.e., being at work but essentially not functioning fully), sub-par educational achievement by children having such conditions leading to a variety of emotional and behavioral problems. Children with poor educational achievement enter a cycle of emotional and behavioral problems leading to risk for delinquent and antisocial behaviors, dropping out of school, eventually affecting the child welfare and juvenile justice systems. This, in turn, becomes a feeder phenomenon into the adult justice system that has seen an increasing number of inmates in prisons and jails with mental and substance use conditions. The U.S. Bureau of Justice Statistics estimated that 16% of all persons in jails and prisons have a mental or substance use disorder. Systematic assessment studies document prevalence estimates that are twice as high, with as many as one in three incarcerated adults and youths having a behavioral health disorder.

An overriding theme throughout the report was that treatment can be effective and that recovery is possible. The report noted that quality problems hinder effective treatment and recovery, noting that numerous studies have shown the discrepancy between what is considered effective care and what is provided, echoing the Quality Chasm report. Low adherence rates to clinical practice guidelines and evidence-based practice standards were noted across major diagnostic categories. For example, adequate adherence rates to established practice guidelines occurred in only 27% of studies covering alcohol withdrawal, bipolar disorder, depression, panic disorder, psychosis, schizophrenia, and substance use.

Parallel programs targeting the same priorities for integrative mental health care in the United States are discussed below.

The Chronic Care Initiatives in Health Maintenance Organizations

These aim to change physician and patient behaviors in several ways, including

- Moving from a focus on a cure to symptom relief
- Expanding the boundaries of care among providers and between traditional medical and social services

Telegram: @medical_k

www.konkur.in

- Making the patient a critical part of the care process through shared decision-making:
  - Creating active roles for the patient's significant others
  - Tying patient satisfaction to clinical outcomes

Building Health Systems for People With Chronic Illnesses

Sponsored by the Robert Wood Johnson Foundation, this program attempts to better coordinate medical and supportive services for the chronically ill and, in so doing, challenges the fact that most insurance systems tend to fund acute care rather than supportive care for individuals with chronic conditions. The program attempts to do the following:

- Integrate services that care is provided across diverse settings; systems of care link clinical and nonclinical support services.
- Reallocate resources by redirecting existing and acute care—focused delivery and financing to serve the chronically ill better.
- Promote early medical and nonmedical interventions.
- Help individuals maintain independence as long as possible in their homes and communities.
- Give the chronically ill and their caregivers a role in designing and improving their health care and support services.
- Support the development of models of care that people with different chronic health conditions can use.

The demonstration program in the accompanying text box set the stage for two operational models for fundamental system changes to improve quality and outcomes. Many proposed and expected system reforms surround efforts to implement the chronic illness care model and the collaborative care model. The chronic illness care model was first elaborated and tested for chronic general medical illnesses such as diabetes, congestive heart failure, and asthma. Recent efforts have attempted to apply the principles of chronic illness care to depression in primary care settings. On the other hand, the collaborative care model was first described and tested for depression in primary care and has been broadened for other psychiatric illnesses that can also be treated in general medical settings with care managers and psychiatrists' support, such as panic posttraumatic stress disorder.

The 2008 Mental Health Parity and Addiction Equity Act

The Mental Health Parity and Addiction Equity Act enacted in 2008—the Wellstone-Domenici Parity Act—tightened the requirements for parity laid out in the Mental Health Parity Act of 1996. Parity was designed to bring individuals with behavioral health disorders into the mainstream U.S. health care system to correct the historical inattention and inequality of care in this population and reduce the

Telegram: @medical_k

www.konkur.in

stigmatization such individuals experienced compared to people having physical health problems alone. The intent was to have behavioral health care benefits equivalent to medical and surgical care benefits. In addition, about two-thirds of primary care physicians had reported difficulty in accessing outpatient behavioral health services for their patients, a rate twice as high as that for other services. Lack of coverage or inadequate coverage, health plan barriers, and a shortage of behavioral health providers were cited by primary care physicians as problems contributing to accessing good behavioral health care. The Mental Health Parity and Addiction and Addiction Equity Act required group health plans with behavioral health benefits to provide the same level of coverage as physical health plan coverage. Access to behavioral health services has been particularly problematic for low-income uninsured and Medicaid patients. Ironically, primary care physicians practicing in areas with many psychiatrists had a greater probability of not securing behavioral health services for their patients because of various plan barriers and the inadequacy of coverage these patients had. Recent studies show that psychiatrists, compared to all other areas of medicine, have the lowest acceptance rate of Medicare (i.e., less than 50% of psychiatrists accept Medicare, with figures lower still for Medicaid). The speculation about such an observation its effect on how other specialties, professionals, trainees, policymakers, and the general population, view adherents to such a practice is important to consider. Some have advocated tying partial or total medical school debt-forgiveness, or even state medical licensure, to having a reasonable percentage of one's practice tied to practitioners seeing individuals covered by Medicare and Medicaid.

The ACT's effect was the practical disappearance of quantitative treatment limits (QTLs), which insurance companies frequently used to limit such treatments and improve coverages for substance use and mental health conditions. More help-seeking in adults suffering from mental health disorders, substance abuse, and eating disorders were noted after parity laws were mandated but with the main caveat that out-of-pocket expenditures also increased. From a limited perspective, the parity acts of 1996 and 2008 were successful. However, from a more global view, they still did not meet the needs of reform in terms of care access, administrative burden, and, more importantly, equity needs (Table 56.2–3).

IMPROVING MODELS IN HEALTH CARE: THE ACA A DECADE LATER

Patient-Centered Medical Homes and Medical Neighborhoods

In 2007, the American Academy of Family Physicians, the American Academy of Pediatrics, the American College of Physicians, and the American Osteopathic Association issued joint principles for the Patient-Centered Medical Home (PCMH), a model to provide comprehensive primary care to children and adults, where appropriate care is structured, delivered, and coordinated around the specific

Telegram: @medical_k

www.konkur.in

needs of each patient. The American Academy of Pediatrics originally developed the medical home model in 1967 for children with special health needs, where it was essential to have a centralized location for a child's medical records. The joint principles of PCMHs (personal relationship with licensed providers, team approach, comprehensive/whole-person approach, coordination and integration of care, quality and safety, expanded access to care, added value recognized, are all hallmarks) cover many of the characteristics of Accountable Care Organizations (ACOs) where PCMHs are seen as the building blocks for ACOs.

Telegram: @medical_k

www.konkur.in

Table 56.2–3.
Summary of the Institute of Medicine's Recommendations of Care for Individuals With Mental and Substance Use Condition

Telegram: @medical_k

www.konkur.in

1. Emphasize patient-centered care and the importance of supporting patient decision making and preferences	The current health systems place a number of barriers to patient-centered care. Insurance discrimination is manifested by less benefit coverage for mental and substance use (M/SU) conditions. There are higher copays for these services. ▶ Clinicians, organizations, accrediting bodies, health plans, and payers need to support a patient-centered care (PCC) approach that respects decision-making capacity of patients. ▶ Stereotypes of patients being unable to arrive at decisions have resulted in coercion of care and discrimination historically.
2. Improve the infrastructure for quality improvement and evidence-based care	Significant problems with the current infrastructure for quality improvement. Assessment and treatment practices not well codified and captured in administrative data sets. Outcome measurements not widely applied; performance measurement for M/SU health care receives insufficient attention in the private sector; public sector efforts have not yet achieved consensus. Quality improvement methods are not permeating day-to-day service. This leads to systems of care that are not based on the principles of quality measurement, and they fail to demonstrate continuous improvement.
3. Coordinate care across systems of care	Poor linkages across systems of care; there is general fragmentation between M/SU and general health care and between mental and substance use care for both children and adults. Unclear accountability for coordination of care among providers.
4. Ensure that the National Health Information Infrastructure Initiative (NHIII) benefits people with mental and substance use conditions	M/SU conditions are not well incorporated into the strategic design of the NHIII. The proposed solutions are as follows: ▶ Charge the Office of the National Coordinator of Health Information Technology and the Substance Abuse and Mental Health Services Administration (SAMHSA) to jointly develop a plan that addresses M/SU health care.

Telegram: @medical_k

www.konkur.in

- Leaders in M/SU health care should become proactive in the national process to set health care data and information technology standards.
- Public and private purchasers of health care should decrease the burden of variable reporting and billing requirements.

Public and private purchasers of health care should encourage widespread adoption of electronic health records, computer-based clinical decision support systems, computerized order entry, and other forms of useful information technology.

5. Increase the workforce capacity

A crisis in the M/SU workforce exists. There is greater variation in the quality of the M/SU workforce than in that for general health care. There are across-the-board deficiencies in education, and there is no “core knowledge” base across disciplines. The resulting variation in licensure, credentialing, and continuing education across disciplines does not assure agreed-on core competencies or adherence to the same standards of practice.

The remedies include the following:

- Creation of an ongoing, federally funded public–private Council on the Mental and Substance Use Health Care Workforce.
- Collaboration of the Council with institutions of higher education, licensing and accrediting bodies, purchasers, and other private sector initiatives developed by the Association for Medical Education and Research in Substance Abuse (AMERSA) and the Annapolis Coalition (http://www.annapoliscoalition.org).

6. Restructure the marketplace to promote incentives for quality and improvement

The Institute of Medicine (IOM) report finds problems in the way in which M/SU care is purchased. Government (state and local) purchasers dominate, and frequently insurance is purchased for M/SU health care separately from general health care. This results in “carve-out” arrangements. Private insurance tends to avoid coverage or offers more-limited coverage to

Telegram: @medical_k

www.konkur.in

individuals with M/SU illnesses. Government purchasers often use direct purchasing by contract rather than insurance arrangements.

- Government should pass laws designed to enact coverage parity by purchasers so that individuals with M/SU conditions are not discriminated against when enrolling in health plans.
- Examples of tools that could be used to bring about parity are risk adjustment, payer carve-outs, risk-sharing or mixed-payment contracts, and benefit standardization across health plans.
- State-level procurement for M/SU care should give the greatest weight to quality and use M/SU health care quality measures in procurement and accountability.
- State and local governments should reduce emphasis on grant-based systems of financing and increase the use of funding mechanisms that link some funds to measures of quality.

Data from the Institute of Medicine. *Crossing the Quality Chasm: Adaptation to Mental Health and Addictive Disorders*. National Academies Press; 2006.

Some of the more recent literature suggested that early PCMH interventions led to only modest improvement in quality and patient experience, with little evidence of effects on costs and no reductions in utilization of hospital, emergency, or ambulatory care services over 3 years. At the same time, these studies suggested that refinement of the outcomes associated with PCMHs was needed and that the development of the NCQA standards for medical home recognition had not been fully developed applied in the early PCMH development. Nonetheless, the studies concluded that further PCMH development and function refinement was necessary.

As the conceptualization of the organization of health care delivery systems developed, it was logical that the PCMH model would expand to include a constellation of entities and activities responsible for the care of populations of patients. Thus, the concept of the Medical Neighborhood was spawned encompassing PCMHs with comprehensive primary, secondary, tertiary services that are community-based, responsive to the needs of individual patients at different times, a truly integrated system of care with good coordination, effective communication, attention to patient education, and cost-effective. Such a concept forms the basis for accountable care.

Accountable Care Organizations

Telegram: @medical_k

www.konkur.in

With the advent of the ACA, the Department of Health and Human Services (DHHS) began developing new approaches in conjunction with the private sector to improve care and to meet the Triple Aim for Medicare and Medicaid recipients. ACOs are voluntary groups of physicians, hospitals, and other health care providers that assume responsibility for a defined population of patients based on the population's use of primary care services. The ACO is responsible for the entire continuum of care that the defined population of patients might need, including access to specialists, social services, public health, and assessment of other socioeconomic factors such as housing, transportation, education, poverty, and nutrition. Providing preventive care for all patients and case management for individuals with chronic diseases is a component of an ACO. If the ACO succeeds in delivering high-quality, improved care at a lower cost, there is an incentive built into the model whereby the ACO can share in the savings achieved through meeting the Triple Aim. Under the ACA, an ACO agrees to manage the health care needs of a minimum of 5,000 Medicare beneficiaries for at least 3 years. Under an ACO, providers are held accountable for the health of their patients and have strong incentives to cooperate and create savings by avoiding unnecessary care (see below). Functionally, ACOs need to be fully integrated through an electronic medical record to share needed information among providers. Different ACO models exist to give hospitals and clinicians choices in working with one another. This process, initiated in 2010, is still ongoing with many hurdles.

The Teaching Health Center

There has been interest in providing post-graduate medical education (post-GME) in the primary care environment of the Federally Qualified Health Centers for some years. These programs have demonstrated that physicians trained in these settings are three times more likely to work in Federally Qualified Health Centers (FQHCs) and twice as likely to serve underserved areas of the country. The ACA provided funds to establish Teaching Health Centers training physicians in nine primary care–related disciplines (including Psychiatry). In the same vein, the IOM issued a report in 2014, "Graduate Medical Education That Meets the Nation's Health Needs," calling for the reform of financing, governance, and transparency of GME. The Report called for a 10-year transition period in which the current funding for more traditional residency programs will be modified. As a result, transformative and innovative residency programs will be created and supported in primary care settings and interdisciplinary organizations providing intensive care programs for persons with severe disabilities and multiple chronic illness conditions.

On the surface, the idea of involving learners in the new model was attractive, but the funding was not consistent, and funding instability limited the impact of this program. It remains an attractive target for further reform. The Teaching Health Center can also meet the need for medical innovation programs in rural areas, improving processes on multiple levels and using alternative funding.

Comparative Effectiveness Research and Patient-Centered Outcomes Research

CER and patient-centered outcomes research (PCOR) are essential to fulfilling each of the three goals of the Triple Aim and correspondingly have been allocated substantial funding support by the ACA through the Patient-Centered Outcomes Research Trust Fund (PCOTF). PCORTF received funds from the general fund of the Treasury and a small fee assessed on Medicare, private health insurance, and self-insured plan revenues. The PCORI received approximately $3.5 billion from the PCORTF over ten years ending September 30, 2019 and used those funds to build the capacity of the health care system to provide and evaluate patient-centered and outcome-driven services. The remaining 80% of PCORTF funds were transferred to the Agency for Healthcare Research and Quality (AHRQ) to support and evaluate PCOR in U.S. health care organizations.

PCOR is intended to provide methods and data repositories that can inform health care services by monitoring key health outcomes. Critical research questions for this agenda include how patients, families, and clinicians deal with the complex and often confusing choices involved in achieving and sustaining health, preventing and treating diseases and other health problems, and accessing and navigating health care systems. Traditional medical research has produced vital advances in understanding disease conditions and their treatment. However, it has not been intended or designed to enhance the current understanding of how patients subjectively experience, participate in and are affected by health care and interactions with health care providers. Patient-centered medical research does exist, but its results typically are not systematically disseminated to either clinicians or patients and families. Research linking the patient's involvement in health care and health outcomes also exists. However, its findings have not been extended beyond demonstrating that a collaborative provider–patient relationship plays a crucial role in patient motivation, adherence, and clinical and functional outcomes. PCOR takes on these critical questions that patients and their clinicians face daily in health care encounters and their personal lives. PCOR is a systematic approach to patient-centered CER, in which patient and clinician preferences, choices, actions, and interactions are studied to determine tools, strategies, resources, and courses of action associated with cost-effective health care outcomes. For patients, PCOR involves testing and then providing guidance about which approaches to care work best, given their particular health conditions, personal and familial concerns, socioeconomic circumstances, and sociocultural preferences. PCOR is designed to provide evidence-based guidance addressing the questions they face daily in practice for clinicians. For insurers, PCOR produces evidence to help them make the best decisions on improving health outcomes for their members while also containing costs, especially with high-burden, high-impact disease conditions.

For psychiatry and the broader mental health field, PCOR provides opportunities and an impetus to conduct real-world clinical research on topics such as these

www.konkur.in

recently funded PCORI projects:

- Integrative Medicine Group Visits: A Patient-Centered Approach to Reducing Chronic Pain and Depression in a Disparate Urban Population
- A Community-Based Executive Function Intervention for Low-Income Children with ADHD and ASD
- Improving Transitional Care Experience for Individuals with SMI
- A Helping Hand to Activate Patient-Centered Depression Care among Low-Income Patients (AHH)
- Integrated Care and Patient Navigators for Latinos with SMI
- Patient-Centered Trauma Treatment for PTSD and Substance Abuse: Is It an Effective Treatment Option?

Pay for Performance, Public Reporting of Performance, and Meaningful Use

The effort to improve quality and, therefore, outcomes has taken many guises, from revamping training to produce clinicians and systems that practice in a quality paradigm to imploring clinicians and systems to do the right thing. At its most basic level, change can also be brought about by behavioral shaping and the use of incentives and disincentives to achieve the desired result—in this case, quality improvement and patient-focused, high-quality care. Two such initiatives, Pay for Performance (P4P) and Public Reporting of Performance (PR), are designed to achieve these results. P4P and PR have been common in physical health care for several years. CMS has adopted P4P and has launched initiatives to demonstrate different ways to implement it. More than half of commercial health maintenance organizations use P4P, and the acceptance of performance measurement among physicians and organized medicine has been acknowledged if not fully realized. P4P and PR, in essence, link physician reimbursement and nonmonetary rewards to improve the quality of care. In addition, physicians recognized for providing high-quality care and more efficient care deliver it at a lower cost than physicians who do not participate.

P4P and PR can reward health plans, provider groups, and individual clinicians in varying ways. Payment is made based on meeting prespecified goals. P4P has had a limited presence in behavioral health, but efforts to expand it into common disorders such as depression and substance use disorders have received considerable attention. For example, a P4P paradigm in behavioral health might involve the percentage of patients diagnosed with a new episode of depression who were treated with an antidepressant at an adequate dosage, who were given the medication for a full 12 weeks; or patients who are given at baseline and subsequently, the Patient Health Questionnaire (PHQ), where the scores are used, along with routine clinical assessment, to track response to treatment over time. If P4P and PR achieve similar penetration in behavioral health care as in physical health care, then the modeling for this approach ideally would begin in training programs.

Telegram: @medical_k

www.konkur.in

In mental health, P4P is risky as it may enhance specific outcomes but undermine the essence of psychiatric treatment and the comprehensive totalistic humane view of the patient. Additionally, it has been linked in nonmedical organizations to increasing employee stress and anxiety, so the effect on physician burnout remains unknown but could be harmful if P4P becomes widely implemented or the de facto practice model. A large meta-analysis of P4P in 12 countries between 2010 and 2018 shows that the effect of P4P is significant if both cost and quality are included but often has unintended consequences and smaller effect sizes than intended.

Behavioral Health Care Services for Children With Serious Emotional Disorders

Children and adolescents with serious emotional disorders (SEDs), such as those with suicidal depression or early-onset psychotic disorders, represent another specialized population. On an annual basis, approximately 2% to 3% of children 3 to 5 years of age and 6% to 9% of children 6 to 17 years of age use mental health services. Of these, only a small percentage is defined as having SED, approximately 0.5%. These children, particularly adolescents, often require complex case management and intensive (e.g., residential or inpatient) services that are costly to provide and pay for.

The most problematic aspect of caring for children and adolescents with serious emotional disturbances is that five categorical agencies are responsible for providing it. Child Welfare has the largest group of these children and the largest budget. Special Education obligations in local school districts are second in expenditures. Mental Health agencies have a clear mandate but less funding despite usually caring for those in greatest need. Juvenile Justice programs serving youth who come before the courts and General Health and Primary Care systems often are the first to identify children with SEDs. However, these tend to operate separately from mental health specialty services and rely on psychotropic medications even though psychosocial treatments are considered the first-line intervention for most pediatric and adolescent psychiatric disorders.

This division of responsibility for child and adolescent services makes it very difficult to organize a coherent delivery system, and in most jurisdictions, confusion and fragmentation are the rule. In the 1990s, following a decade of National Institute of Mental Health (NIMH) planning grants, the Robert Wood Johnson Foundation developed the Mental Health Services Program for Youth (MHSPY) to come up with coherent systems of care for children with SEDs and their families, integrating the efforts of the responsible agencies at the community level. This was followed by a large grant program by the Substance Abuse and Mental Health Services Administration (SAMHSA). A number of the more than 80 communities that received these grants have developed advanced care management program models providing individualized, intensive care services to children (and their

Telegram: @medical_k

www.konkur.in

families) who might otherwise have been confined in institutional settings. Services under these models are often funded by risk-adjusted case rates derived from the blending of funds from different agencies' budgets and often administered by the Medicaid program. A compelling high-cost, high-need group that can potentially benefit from the integrated care provided under health homes is children with SEDs were identified in a 2014 policy brief by the Center for Health Care Strategies as:

> The Medicaid health home state plan option is designed to provide a comprehensive system of care coordination across medical, behavioral, and long term services and supports for Medicaid beneficiaries with chronic physical or serious mental health conditions . . . states can tailor behavioral health-focused health homes to meet the unique needs of both children and adults. (Center for Health Care Strategies 2014 policy brief. https://www.chcs.org/media/Developing_Health_Homes_for_SED_02_27_14.pdf.)

The health home is envisioned as a comprehensive set of services that wrap around the patient and address the full range of complex health problems. This could include pediatric, psychological, educational, behavior modification, case management, social work, family therapy, child welfare, legal/juvenile justice services, and psychiatry for children with SEDs. When working within the health home rubric with children, psychiatrists play a vital leadership role in collaboratively informing and coordinating with multiple behavioral health and social/educational services providers as well as with the pediatric primary care provider.

HEALTH INFORMATION TECHNOLOGY (HIT) AND ELECTRONIC HEALTH RECORDS (EHR)

> "By computerizing health records, we can avoid dangerous medical mistakes, reduce costs, and improve care." *President George W. Bush, State of the Union Address, January 20, 2004.*

Two successive administrations, Bush and Obama, have taken on the task of improving health records and communications. The 2009 American Recovery and Reinvestment Act (ARRA) and the related Health Information Technology for Economic and Clinical Health (HITECH) Act were designed to improve the widespread implementation of electronic health records. These acts represent wide-ranging public investments to help expand EHR utilization and expand HIT use to big data analysis. By modernizing the health care field, the hope is to improve population health, decrease medical errors, streamline financial reimbursement, and streamline billing activities. Another advantage of HIT adoption is the creation of more jobs in that health care technology sector, thereby simplifying and vitalizing a new economic sector that, until ~2008, was fairly limited. Expansion of that sector benefits HIT vendors, the data analytics sector, academic medical centers, professional bodies, and universities.

On the other hand, HIT could see major expansions with the advent of machine learning and the possibility of data mining through EHRs to find population health

Telegram: @medical_k

www.konkur.in

trends and improve them.

The most basic use of HIT is to transition from paper charting to electronic charting. The transition was spurred by the belief that EHRs would help decrease medical errors and enhance care collaborations. To achieve high use, governmental push included redefining “meaningful use,” then financial incentives and later penalties for nonuse.

The concept of meaningful use is embedded within the ACA. Meaningful Use entails financial incentives for providers (professionals and hospitals) in their “meaningful use” of certified *electronic health records* (EHR) to improve patient care. Examples of Eligible Professional Core Objectives are: use of computerized physician order entry (CPOE) for medication, laboratory, and radiology; generating and transmitting permissible prescriptions electronically (eRx); recording specific demographics (preferred language, sex, race, ethnicity, date of birth); recording smoking status for patients 13 years old and older; use of clinical decision support to improve performance on high-priority health conditions; a provider who receives a patient from another setting of care or provider of care should perform medication reconciliation; a provider who transitions their patient to another setting of care or provider of care or refers their patient to another provider of care provides a summary of care record for each transition of care or referral.

In addition, to receive an incentive payment, providers are required to submit Clinical Quality Measure (CQM) data through the EHR that measure and track the quality of health care services. These include health outcomes, clinical processes, patient safety, efficient use of health care resources, care coordination, patient engagements, population and public health, and adherence to clinical guidelines.

The effect of EHR implementation on medical practice has been profound. The first impact has been a change in how physician–patient encounters are conducted. Over the past two decades, the length of the average ambulatory experience has decreased to less than 13 minutes. In parallel, rates of burnout in physicians have grown as EHR use has become commonplace. An analysis of time spent with patients versus completing EHR/bureaucratic tasks indicates that up to 50% of encounter time is used to complete those tasks, and most physicians chart 1 to 2 hours after the workday is over. No EHR seems to have significantly better satisfaction or less burnout than others. The trend of EHR adoption also coincided with an increased emphasis on patient satisfaction. However, patient satisfaction depends mainly on a higher percentage of gaze level from the physician. Some literature from 2000 to 2015 encourages physicians to multitask better to meet the need for patient eye contact and keep the human touch in the clinical encounter. However, there is a growing awareness of the transformation of the clinical encounter in the past few years and that burnout was reaching nationwide severe proportions. Physicians who have to continue/finish their charting at home have increased odds of burnout and HIT-related stress. Patient satisfaction tends to drop when there is a switch from paper charting to HER, potentially reflective of the change in human interaction level. Therefore, as a

Telegram: @medical_k

www.konkur.in

significant reform move, HIT has transformed medicine as we know it, with some positive and some very significant negative, unintended consequences. Some of these consequences can be mitigated with training to enhance documentation quality, readability, and clinical accuracy. Training can lead to fewer medical errors and increased efficiency in chart review and data retrieval; however effective trainings are few and far between, and on a national level, physicians still rate EHR as a major reason for burnout. This is especially true in primary care specialties, and job satisfaction is related to HER satisfaction in some cases. The impact of trainings and other HER improvement strategies on burnout range from about 5%. In psychiatry, specifically, HER has transformed and quasi-annihilated the therapy experience, though, for fairness, it is necessary to point out that the demise of psychotherapy administered by psychiatrists started with managed care, another wave of reform that preceded the HIT/HER implementation. Most depression treatment has turned to psychotropic prescribing in the past two decades with a concomitant decrease in psychotherapy. While one cannot pinpoint a single factor as responsible for decreasing psychotherapy rates, a plethora of factors, including the change in physical settings needed to implement HER, may have contributed, as well as workflow disruptions. Interestingly, a measure of dissatisfaction with HER is that patients consistently overestimate the amount spent by physicians on HER.

The experiment with HER is significant as HIT can further modify the medical experience, HER modifications focusing on higher-level cognitive tasks and improved team communication may help, and improved patient portal usage to help with health maintenance.

The next stages for HIT expansion are big data analysis and health outcomes optimization via data mining and patient-reported outcomes (PROs). From a systems perspective, the quasi-universal use of HER and the level of acceptability in patients makes it possible to use it for (1) PROs so that clinicians do not have to ask questions in session as much, (2) Diagnostic validation, and (3) Interface with applications and wearables outside of session. All these goals are still years away but are abundantly discussed as the next frontiers in HIT and the improvement of health care. The PCORI is an excellent resource to guide this field development effort. The Users' Guide to Integrating Patient-Reported Outcomes in Electronic Health Records aims to outline a map of PRO-EHR integration across the planning, selection, and engagement areas.

In order to properly use PROs, careful selection of what outcomes to use has to occur first. The outcomes must be clinically meaningful, have some expected impact over the disease course or illness treatment decisions, or patient self-efficacy, and present a reasonable burden for patients regarding time and accessibility. For psychiatric illnesses, substance use disorders, mood symptoms, and medication adherence are obvious choices. Regardless of challenges, the potential for large-scale data collection and standardization is obvious with HER integration. This innovation will pave the way for effective population surveillance.

Telegram: @medical_k

www.konkur.in

Second, patient engagement is crucial and may highlight socioeconomic and educational status disparities. While smartphone ownership is quasi-ubiquitous, technical literacy is still subject to socioeconomic and age disparities, with younger, wealthier individuals being more technology-savvy. Individuals with psychotic disorders and severe depression, catatonia, or mania may not fully engage in PRO collection or use and may need separate workflows; these challenges are specific to psychiatry and specifically to those working with populations with severe mental illness. Specifically, smartphone ownership and app usage are shown to be much less in individuals with psychotic disorders than those without, and this could be related to the nature of their illness, with paranoia and delusions centered around the information being collected, the effect of magnetic waves from the phone or wearable, and the way information will be used.

Third, the field currently lacks guidelines to support PRO meaningful interpretation. For example, patients logging their mood or filling out a mood questionnaire cannot get a personalized, treatment-driven interpretation of their symptoms. The information must be available to their clinician to be usable, which requires interoperability with EHR. Last, the liability of clinicians and health care systems of PRO-generated info is not tested yet. One can think of scenarios when PRO include mood deterioration or suicidal ideations preceding an adverse outcome such as a completed suicide. This area is unexplored yet, and there are no guidance measures to lead psychiatrists to use apps, wearables, or PRO portals from their institutions for patient care.

Accessing patients to their PRO and interpretation of information provided is a field of its own, currently undergoing extensive growth. The federal laws protecting patient access to their medical record should cover that, but again, this is an expanding area with no formal guidance. In order for the next HIT revolution and reform to occur, specifically in the context of having patients fill in PRO, several steps have to be formalized:

- The health system culture has to acknowledge the importance and usefulness of PRO and support the use of PROs.
- Health systems have to invest in PRO collection as a necessary means to help patients and clinicians improve population health one individual at a time.
- Training and efforts to promote this culture change, including cost and time requirements, must be provided. On a more psychiatry-specific and disease-specific level, a framework to build notification procedures and modalities and identify the appropriate recipients to receive notifications for PRO data will be needed (who will be on call for late evening patient digital alerts?). In certain situations, alert fatigue may become a theoretical possibility, as with personality disorders patients.

A Further EHR-HIT reform element is the allocation of wearables to monitor health outcomes when patients are in their natural environment. This is far from reality in psychiatry but is, like PROs above, being discussed and planned as the

Telegram: @medical_k

www.konkur.in

next step in patient-centered population improvement relying on real-time data. Areas of interest identified in order for this transition to be successful include "device type, communication interface, data transfer protocol, smartphone and/or PC integration, direct integration to open health platform, 3rd platform integration with open health platform, support for health care system/middleware connection, recorded health data types, integrated sensors, medical device certification, whether or not the user can access collected data, device developer access, and device availability on the market." At this point, those measures are best suited for physical illnesses with well-defined physiologic markers that can be used to build machine learning algorithms, for example, heart rate, blood pressure, or blood sugar.

In conclusion, the issues involved in reforming health care are complex and transformational. They have the potential to change the way medical encounters are conducted.

Effective reform requires the expertise of a broad range of disciplines, from economics to ethics to basic public philosophy, and effects take decades to show. Therefore, psychiatrists must remain an integral part of the conversation as users of the system and as physician leaders and be ready with a clear vision and meaningful participation in the national health care dialogue.

56.3 The Role of the Hospital in the Care of Persons with Mental Illness

ERICA TAYLOR, M.D., M.P.H.

Throughout the 19th century and for the first half of the 20th century, public psychiatric hospitals (and some private ones as well) provided all the roles necessary to take care of psychiatric patients. The state hospital was the source for inpatient, outpatient, case management and outreach, and emergency services. If someone needed admission, a family member could simply transport him to the front door. With the shift from inpatient to community-based services that began in earnest in the mid-20th century, admission to, discharge from, and services within the psychiatric hospital became both more complex and more convoluted. Layer upon layer of agencies, services, and regulations facilitated and impeded the psychiatric hospital in its mission (Fig. 56.3–1).

The reasons for the evolution of this relationship between the psychiatric hospital and its prospective and actual patients are multifactorial. As Figure 56.3–1 illustrates, there are entities with overlapping but competing agendas at every turn. Fundamentally, there are two predominant factors that account for the contemporary, tortuous, labyrinthine interface between the psychiatric hospital and the community. First, the psychiatric hospital, in a manner quite distinct from the general hospital, plays two roles: clinical services and public safety, thus, the extensive interface between the psychiatric hospital and the criminal justice system (see Fig. 56.3–1). And second, psychiatry, more than any other field of medicine, has been inundated by gyrations of conflicting actions to decrease the cost of care and treatment, thus the barriers and alternatives to psychiatric hospital admission (see Fig. 56.3–1).

Telegram: @medical_k

www.konkur.in

FIGURE 56.3–1. The psychiatric hospital in the context of the community.

The first one-and-one-half decades of the 21st century have not been kind to psychiatric hospitals. Virtually every state in the United States is experiencing a shortage of psychiatric beds. These shortages include acute care beds, intermediate and long-term care beds, and forensic beds. The effects of these bed shortages are increased waiting lists for state hospital beds, increased waiting lists for other psychiatric beds like general hospitals and Veterans Administration (VA) psychiatric beds, overcrowding in state hospitals, backups, and boarding in general hospital emergency departments (EDs), and premature discharges from acute care settings. These shortages have also meant a shift of persons with serious mental illness (SMI) behind locked doors from public hospitals to jails and prisons. These psychiatric bed closures come from all types of hospitals. Sixty-four percent of states have experienced declines in the number of general hospital specialty unit psychiatric beds, and 19 states have experienced a decline in the number of private psychiatric hospital beds. Nationwide, the number of state and county hospital beds declined by 86% (369,999 to 52,612) between 1969 and 2002; the number of VA medical center (VAMC) psychiatric beds declined by 84% (51,696 to

Telegram: @medical_k

www.konkur.in

8,386) within the same time period. The inaccessibility of psychiatric beds is a regular feature in news stories and editorials, often with a link between that and a local or national tragedy.

Lengths of stay have plummeted. Between 1990 and 2010, the length of stay of hospitalizations for SMI in acute care settings decreased by 50% (from 14 days to 7 days). Private insurers represent a shrinkage percentage of payments for hospital services, especially for substance abuse services. About 50% of all payments for psychiatric inpatient services were from government programs; state governments' funding increased by 65% just between 2000 and 2001.

Hospital-based outpatient services grew by 78% (242,301 episodes to 1,104,300) between 1969 and 2002. In 2002, however, hospital-based outpatient services represented only 31% of all outpatient episodes of care for psychiatric disorders.

The shift of resources from hospital to nonhospital services is reflected by the changing distribution of expenditures by state mental health authorities (SMHAs). Inpatient services received 63% of the SMHA budget in 1981, 50% in 1993, 28% in 2004, and 23% in 2012. Although the overall inpatient percentage decreased, the proportion going to forensic patients increased to 33% of all state hospital expenditures.

While there has been a shift in public expenditures from inpatient to outpatient services, there has been an overall decrease in public expenditures for psychiatric treatment. In fiscal years 2010 and 2011, the biggest cuts were directed at state hospitals with 20 and 15 states, respectively, cutting state hospital funding. Less funding meant fewer individuals could be serviced in state hospitals, with 31 states decreasing the persons they admitted comparing 2007 to 2009.

At the same time, the demand for state hospital utilization increased in 18% of the states, in part because states were also making cuts in all manner of community-based services. Between fiscal years 2009 and 2011, 17 states had cuts in their overall state mental health expenditures by greater than 1%, with 5 of those states exceeding 20% (1 state approached 50%).

Marshaling scarce resources has led to synergies among various sectors within a state. In just more than 75% of the states, community-based programs (often at general hospitals) perform a gate-keeping function to state hospital entry. Some states (38%) require general hospital admission prior to a transfer to a state hospital. And in all but five

Telegram: @medical_k

www.konkur.in

states, there are assisted outpatient commitment (AOT) (involuntary outpatient commitment) laws on the books with an expectation these can be used to decrease both inpatient and overall mental health services costs.

The picture does not look optimistic, at least for the immediate future. About half of the states are reorganizing their state hospitals, including downsizing, reconfiguring, closing, and/or consolidating. Despite this, 11 states still have 6 or more state hospitals each. And a surprising number of states are building new state hospital buildings, but these generally replace one or more existing state hospitals and usually do not reflect an increase in beds (see Table 56.3–1). As more patients are admitted under forensic commitments, lengths of stay increase, and so does the unavailability of beds to others. In 2006, about 40% of patients found not guilty by reason of insanity had lengths of stay of 1 to 5 years, and about 38% had lengths of stay of greater than 5 years.

While the place of psychiatric hospitals as a tool in the resources box of treatment for mental illness is shrinking, the need is growing. On any given day in the fiscal year 2010, the number of noninstitutionalized individuals with an episode of serious psychological distress in the past was 3% of the population. In 2012, 4.1% of the adult U.S. population had an episode of SMI in the past year. The 12-month prevalence for schizophrenia in adults was 1.15%, while it was 3.5% for post-traumatic stress disorder (PTSD) (one-third of these classified as severe), 9.1% for any personality disorder, and 18.1% for anxiety disorder (23% of these classified as severe). The mismatch between need and services is no better represented than by the fact that in 2008 over 40% of adults in the United States with an SMI did not receive any treatment for a mental health problem. Of those that did, 7.5% had an inpatient, and 40.5% had an outpatient episode of care.

The state of hospital psychiatry raises questions about how it came to play the roles it does. What were the historical influences that brought the psychiatric hospital to where it is, and what keeps it there? How does the psychiatric hospital (this term will include general hospital psychiatry units) fulfill its current role? And what should be the roles of psychiatric hospitals in the future?

THE HISTORICAL EVOLUTION OF THE ROLE OF THE HOSPITAL

Telegram: @medical_k

www.konkur.in

Prior to the 19th century, the care of insane persons was custodial in nature, took place largely in almshouses, and was predominantly a local endeavor. State care, in the beginning, meant an institution established, built, and managed by the state but whose operation was not funded by the state. Payers were, in descending order of priority, the patient, the family, and the county. The earliest public facilities—in Williamsburg, Virginia, and Columbia, South Carolina—functioned in this manner. The state taking responsibility for all insane persons and performing its responsibility through state-managed and funded hospitals began with Worcester State Hospital in 1833.

Before there were any more than a few public hospitals, there was already a well-established group of private psychiatric hospitals. Three of these began as parts of general medical hospitals: The Institute of the Pennsylvania Hospital, Bloomingdale Hospital (New York), and McLean Hospital (Massachusetts). Three more were freestanding institutions: Butler Hospital (Rhode Island); Brattleboro Retreat, which began as the Vermont Asylum for the Insane; and the Hartford Retreat, which subsequently was renamed the Institute of Living (Connecticut). Two of the hospitals began under the aegis of religious organizations: The Friends Asylum (Pennsylvania) was initiated by a Quarterly Meeting of the Philadelphia Society of Friends, and the Mount Hope Institution (Maryland) was a Catholic hospital that began as the Mount Saint Vincent Hospital.

Of these larger private facilities, all but one preceded the state's first public hospital, sometimes by more than 50 years. The private hospitals helped the state to meet its obligations to the insane poor by admitting "public" patients. Payments were made by the state to the private facility, and some treatment was given without charge. Thus, the states' purchase of beds from the private sector was not a novel concept of the late 20th century but is actually how U.S. hospital psychiatry began.

Many public and some private hospitals throughout the country were built under a design put forth by Thomas Kirkbride, a founding member of the American Psychiatric Association (APA). In his book, *On the Construction, Organization, and General Arrangements of Hospitals for the Insane*, Kirkbride prescribed every aspect of hospital construction and operation. His prototype hospital, variations of which can still be seen across the United States (but are fast being torn down), is shown in Figures 56.3–2 and 56.3–3. Noteworthy among his recommendations is

Telegram: @medical_k

www.konkur.in

that a 250-bed hospital would have 16 wards, with about 15 patients per ward.

Texas: University Behavior Health Denton—opened 2005, bed 104.

By the 1880s, most psychiatrists agreed that "insane patients can best be managed away from their own homes." Parsons, an alienist of the era, opined, "well-equipped and well-managed asylums for the insane are among the most important of the outgrowths of modern civilization and benevolence." By the end of the 19th century, it was clear that private facilities were for the wealthier, more genteel class of citizens, who were able to pay fees and were provided remarkably comfortable accommodations. Public hospitals were entities of the state, county, or municipal governments that served not only the poor but also the middle class, given that the latter could not afford private hospitals.

A major difference between the public and private facilities is that public institutions sought to lower their censuses as state hospital populations grew and patients had progressively longer lengths of stay, whereas private facilities sought patients to maximize their occupancy rates. A fundamental criticism of private facilities was pointed out by Parsons: "It is not for the interest of the proprietor of a private asylum to cure his patients, and hence they may not make an honest effort to promote their cure." Much of what many consider to be modern developments in hospital psychiatry were well under way before the end of the 19th century: Oversight of private hospitals by state boards, advertising by private hospitals, involuntary admissions to private hospitals, more perks for higher fees, and the "dumping" of patients from the private to the public sector.

Work and recreation were both seen as important to the mental health of patients in the 19th century. Generally, the public hospitals did better with the former, and the private ones with the latter. Recovery, employment, and wellness are not novel ideas of contemporary hospital psychiatry. Each was endorsed more than 150 years ago in both public and private hospitals.

Nor is evidence-based psychiatry a new thought. Andrews articulated in 1887 that "the unparalleled progress in neurology, cerebral anatomy, physiology, pathology, and localization of function has enlarged the horizon of our knowledge of disease and of the action of causes." This

Telegram: @medical_k

www.konkur.in

progress, he said, “furnished a scientific and positive basis for treatment in many cases of insanity which before was unattainable.” Inpatient treatments near the end of the 19th century included such modalities as electricity, massage, oophorectomy, enforced rest, hydrotherapy, and physical training.

Changes in hospital psychiatry over the first half of the 20th century were dramatic. Psychoanalysis was introduced to the inpatient setting in the 1920s and somatic treatments such as insulin coma, Metrazol shock, and electroconvulsive therapy in the 1930s. In the 1940s, attention was focused on developing milieu therapy, whereas in the 1950s, the introduction of the first antipsychotic medication, chlorpromazine, fundamentally altered inpatient psychiatry.

FIGURE 56.3–2. Exterior of hospital prototype designed by Thomas Kirkbride. (From Kirkbride TS. *On the Construction, Organization, and General Arrangements of Hospital for the Insane*. J.B. Lippincott; 1880.)

The mid-1950s began the shift from hospital-based to nonhospital-based care and treatment of persons with mental illness, a movement retrospectively labeled “deinstitutionalization” but perhaps better termed “dehospitalization.” General hospital psychiatry and day hospitals became major loci of care and treatment, and the role of the psychopathic hospital expanded. Units in general hospitals were not always welcomed by hospital medical staff, who were concerned that psychiatric patients,

Telegram: @medical_k

www.konkur.in

whom the physician thought would overwhelmingly be noisy, destructive, violent, or suicidal, would disrupt the general hospital.

FIGURE 56.3–3. Interior of hospital prototype designed by Thomas Kirkbride. (Kirkbride TS. *On the Construction, Organization, and General Arrangements of Hospital for the Insane*. J.B. Lippincott; 1880.)

The darkest era in U.S. hospital psychiatry was in the 1940s, a time when the care of persons with mental illness was described as a national disgrace. Attempts were made to improve inpatient treatment through the promulgation of principles and standards, such as those put forward by the Division of Mental Hygiene of the U.S. Public Health Service, the National Committee for Mental Hygiene, and the APA's Committee on Psychiatric Standards and Policies. These probably had less effect than exposés such as Mary Jane Ward's *The Snake Pit*, a fictionalized first-person account of life in a state hospital.

Whereas the public sector was overburdened and overrun, by 1950, the private sector was also facing financial difficulties. The Medical Director of McLean Hospital stated at the 1950 APA Institute, "The time when you could run a private hospital as a hospital and make money has gone. Operating expenses have so increased that it is almost impossible to collect the cost from our patients."

In the 1960s, as health insurance for hospitalization expanded to include psychiatric treatment, psychiatric hospital treatment outside of state hospitals became more available. Misuse of insurance for hospitalization for mental illness was quickly recognized. To remedy the manipulation of hospital benefits, interventions were introduced: Peer review, reimbursement for partial hospitalization, and reimbursement for

Telegram: @medical_k

www.konkur.in

other alternatives to inpatient treatment. “Dumping” and “cost-shifting” emerged as part of the everyday life of inpatient psychiatry.

In the 1970s, states were contemplating phasing out state hospitals. General hospital psychiatric units were becoming more of a presence. The expanding role of general hospital psychiatry drew caution from some who warned workers in general hospitals to be watchful of efforts to convert general hospital psychiatric units into mini-state hospitals. Declining numbers of individuals willing or able to pay for private hospital treatment and more available third-party coverage led private hospitals to admit patients of different socioeconomic classes and ethnic backgrounds and to keep all patients for shorter lengths of stay.

In the 1980s, there was a remarkable growth in private sector hospital beds. Private corporations were rushing to build psychiatric hospitals as less regulation, lower overhead, and greater latitude in insurance reimbursement meant there were huge profits to be made in the “psychiatric hospital industry.” For-profit psychiatry grew, but with it came a new set of problems. For-profit hospitals were the least likely to treat the most functionally disabled; would treat few if any patients who could not pay for treatment; usually had poorer staff-to-patient ratios than nonprofit hospitals; failed to provide education and training; failed to contribute adequately to research, and overall provided a lower quality of care. These hospitals tended to be totally disengaged from the communities in which they were located; they paid higher salaries and thus hired away graduating residents from academic and public sector positions.

The heyday of for-profit hospitals (most private psychiatric hospitals) did not last long. Throughout the 1990s, the total and the average number of beds per private hospital decreased, as did the average length of stay. Between 1992 and 1998, private psychiatric hospital beds declined by 23%. For-profit companies had built “chains” of hospitals so rapidly that there quickly came to be too many private psychiatric beds, and hospital chains began experiencing major financial losses. Lawsuits against the chains for unscrupulous practices such as recruitment of patients and manipulative billing practices were settled in the hundreds of millions of dollars.

The 1990s also witnessed the privatization of public mental health services. Medicaid, Medicare, and state funds were directed to the private sector to greater degrees during the 1980s and 1990s. States assisted freestanding private hospitals in obtaining waivers of the Institution for

Telegram: @medical_k

www.konkur.in

Mental Disorders (IMD) rule (see later discussion). A greater reliance on the private system for those formerly treated in the public system created many unintended consequences that varied state by state, including inpatient treatment further from one's community, less continuity of inpatient treatment, new patterns of recidivism, and certain patients being blacklisted at some hospitals.

In 2001, 37% of general hospitals had psychiatric inpatient care. This percentage is higher than those with a psychiatric emergency, consultation-liaison (C-L), or even outpatient services. Hospital psychiatry in the United States continued to be a *business*. However, in the business of psychiatry, nonprofit psychiatric care providers compared favorably with for-profit providers.

It is interesting to note how the practice of hospital psychiatry appears to have shifted in response to shorter lengths of stay. A study at McLean Hospital in 2002 that compared inpatient antipsychotic medication use in 1989, 1993, and 1998 showed the chlorpromazine-equivalent final total dose of all antipsychotic medications used at discharge in 1998 was 29.3% greater than in 1993 and 46.1% greater than in 1989. The average time from admission to first antipsychotic dose decreased dramatically from 6.8 days in 1989 to 1.5 days in 1993 and .9 days in 1998. Two or more antipsychotic medications were used during 20% of inpatient days in 1998, compared to 5.7% days in 1993 and 1.7% in 1989. Pressures to discharge patients reduced not only the length of treatment but also the content of treatment.

In the first decade of the 2000s, the prospects for the private psychiatric hospital and for general hospital psychiatric units did not look good. Although overall health care spending increased by 15.7% between 1992 and 1999, mental health and substance abuse spending decreased by 17.4%. Behavioral health care spending went from 7.2% of total private health insurance spending to 5.1% over this same time period. Reimbursement rates fell such that they often did not even meet the total costs of care and treatment. While reimbursement rates fell, costs to deliver treatment increased.

Private hospitals were offering fewer services. Those hospitals offering partial programs decreased from 82.5% to 66.7%, and those offering outpatient services dropped from 64.2 to 49.2% between 2000 and 2001. At the same time, oversight increased. The Office of the Inspector General (OIG) of the Department of Health and Human Services, the Joint

Telegram: @medical_k

www.konkur.in

Commission on Accreditation of Healthcare Organizations, and the Center for Medicare and Medicaid Services all stepped up investigations of hospitals. Medicaid's progressive decrease in disproportionate share payments (DSHs) to public mental hospitals is taxing some states' ability to operate their public system at its pre-2000 scale.

The landscape of U.S. inpatient psychiatry became so rough that well-established private hospitals closed or moved. Those in the former category include Taylor Manor and Chestnut Lodge in Maryland. In the latter category, the best known is the Menninger Clinic, formerly of Topeka, Kansas, and now in Houston, Texas. In the public sector, state hospitals, well established since the 19th century, began reinventing themselves, usually by the consolidation of multiple public hospitals and by new construction such as Worcester State Hospital (Massachusetts), Oregon State Hospital, and Western State Hospital (Virginia). Furthermore, the need to serve and contain persons with mental illness and histories of sexually problematic behaviors is diverting resources from the treatment of psychiatric disorders. California built a 1,500-bed facility for forensically committed individuals—mostly sexually violent predators—representing the first new California facility in more than 50 years. Even older adult individuals with such histories can often not be discharged from the public psychiatric hospital as federal law prohibits nursing homes from admitting persons who are classified as the highest level of sex offenders.

As components of psychiatric services in the second decade of the 21st century, psychiatry hospitals are shrinking, growing, being torn down, and being newly built all at the same time. As hospitals are unable to meet the needs of the population requiring inpatient level of care, local police have become the triage agents for persons with serious mental illness in the streets; jails and prisons are unofficial replacement facilities for state hospitals, and mental health courts provide more case management than anything else. One potential positive note is the growing number of new public psychiatric hospitals built with the hope that the building's design will facilitate patients' recovery (see Table 56.3–1). It is well worth remembering, however, the observation made in the wake of newly constructed community mental health centers (CMHCs) with inpatient units in the 1970s: the latest in "psychoarchitecture" and design elements do not result in behavioral remediation since clinical improvement does not result simply from changing bricks, mortar, and furniture. That being

Telegram: @medical_k

www.konkur.in

said, newly built hospitals, most of which have had significant problems with translating programmatic and life safety design concepts into actual hospital structures, have brought more pleasant surroundings, in an overall safer environment, with more available space for in- and outdoor programming (see Figs. 56.3–4 and 56.3–5). These figures are presented as an example and not as a model.

FIGURE 56.3–4. Worcester Recovery Center and Hospital (WRCH). Exterior view.

Available psychiatric beds in general and private hospitals appear to be made inaccessible to patients by insurance providers because limiting admission to hospitals with which they have negotiated rates is one means to control cost. As reimbursement rates drop below the actual expenditures of the general hospital, these hospitals limit the third-party payers with which they will contract or further reduce or eliminate psychiatric beds, exacerbating the bed shortage.

Public psychiatric beds are highly disproportionately occupied by forensically committed patients. This makes beds for civil admissions less available, and patients are stuck in general or private psychiatric hospital beds, which in turn delays the movement of psychiatric patients needing

Telegram: @medical_k

www.konkur.in

admission out of the ED. Waiting time in an ED can be up to 1 month for a psychiatric bed, or the patient is prematurely discharged from the ED, sometimes with lethal consequences.

Despite ascriptions of causality for the current state of hospital psychiatry to malevolence, malfeasance, and malversation, it would seem more accurate to see the role of the psychiatric hospital in the second decade of the 21st century as still the result of a basic tension between clinical benefit, social control functions, and parsing out of costs. Each governmental level and each government agency wants another one to fund the treatment of mental illnesses.

Despite all of these uncertainties, there is no indication that psychiatric hospitals will cease to play some role in the future. The remainder of this section focuses first on defining the role of the hospital and then on implementing that role.

DEFINING THE ROLE OF THE PSYCHIATRIC HOSPITAL

Clinical Rationale

The clinical rationale for the role of the psychiatric hospital was well established by the mid-18th century. Edward Jarvis, a nonpsychiatrist physician, well enmeshed in the psychiatric care of his era, stated it as well as anyone. First, Jarvis discussed his thoughts on “diseases of the mind”:

> Maladies of the mind, like those of the body, require that the causes that produced them shall cease to act upon them. Unfortunately the diseases of the mind frequently find their origin in the circumstances and associations of home, in the cares and anxieties of business, in the relations of neighborhood, in the affairs of the town, in the movements of religious, political or other associations, in the habits of indulgences which are practiced. Or when the diseases are once established, they may be kept up by some of these. Moreover, the natural perceptions and moral sensibilities being disordered, the scenes, circumstances, and the persons, which are usually agreeable and favorable, in health, become objects of aversion and sources of irritation and keep the disorder alive. (Jarvis E. *Address Delivered at the Laying of the Corner Stone of the Insane Hospital, at Northampton, Massachusetts.* J&L Metcalf; 1856.)

Then Jarvis provided his thinking on why hospitals were needed to treat persons with these diseases:

Telegram: @medical_k

www.konkur.in

As the lunatic cannot be separated from these, while in his own house, he must go from them and generally among strangers. It is needful that the mentally disordered not only go away from home, but be placed where all the circumstances and associations are different from those to which he has been recently accustomed, and where all the influences that may reach him, can be controlled and modified, so that none but such as are favorable may affect him. They will be found in the hospital [where] the officers and the attendants are selected on account of their peculiar fitness for their work. They have the high intelligence, the scientific knowledge, and the moral endowments of gentleness, and firmness, and sympathy that are required, and they know how to occupy the diseased mind and lead it from its morbid fancies, and fix it upon cheerful and satisfactory subjects. (Jarvis E. *Address Delivered at the Laying of the Corner Stone of the Insane Hospital, at Northampton, Massachusetts.* J&L Metcalf; 1856.)

FIGURE 56.3–5. Worcester Recovery Center and Hospital (WRCH). Interior view.

Jarvis provided a quite optimistic prognosis if his recommendations were followed, but one quite consistent with those of his professional colleagues: “If insane persons are allowed to enjoy the means of healing in the early stages of their disorder, within one year after it appears, about

Telegram: @medical_k

www.konkur.in

75 to 90 percent, can be restored to health." Furthermore, he argued for prompt hospitalization with the onset of symptoms:

> But in this class of maladies, time makes rapid havoc and diminishes the chances of cure. If the means of healing are not tried within the first year, the ratio of cures is reduced perhaps a half in the second and still more in the third year, and when five years of neglect shall have elapsed, the hope of restoration is reduced to a mere accident, which no human skill can promise to accomplish. (Jarvis E. *Address Delivered at the Laying of the Corner Stone of the Insane Hospital, at Northampton, Massachusetts.* J&L Metcalf; 1856.)

By the mid-19th century, it was also clear to those who treated persons with insanity that the hospital had much to offer those in need of acute treatment due to advances in the field. Samuel Woodward, the first president of the APA, noted the following in 1846:

> The abandonment of depletion, external irritants, drastic purges, and starvation, and the substitution of baths, narcotics, tonics, and generous diet, is not less to be appreciated in the improved condition of the insane, than the change from manacles, chains, by-locks and confining chairs, to the present system of kindness, confidence, social intercourse, labor, religious teaching, and freedom from restraint. In this age of improvement, no class of mankind have felt its influence more favorably than the insane. (Woodward SB. Observations on the medical treatment of insanity. *Am J Psychiatry.* 1850;7(1):1–34. doi: 10.1176/ajp.7.1.1.)

Hospital treatment continued to improve in the mid-19th century. Charles Nichols, superintendent of the Government Hospital for the Insane (St. Elizabeth's), commented as follows in the 1870s: "Much less mechanical restraint, and much less seclusion are now used in our institutions for the insane than were formerly resorted to in them. . . . I trust that we shall be able to still further reduce the proportion of cases in which restraint will be deemed advisable."

The role the physician could play in the hospital was also clear by the mid-19th century. Luther Bell, superintendent of the McLean Asylum, indicated in 1849:

> Domiciliated with our patients, ready at all hours, by day or night, to watch the effect of our prescriptions, sure of their being fairly and fully carried into effect, without hazard of the interference of timid friends or unfaithful nurses; obliged to make no disguise, no prescription for form or appearance sake, it is in our power to follow out the best convictions of our judgment, uninfluenced by aught extraneous to the object desired. (Bell LV. On a Form of Disease resembling some advanced stages of mania and fever, but so contradistinguished from any ordinarily observed or described combination of symptoms, as to render it probable that it may be an overlooked and hitherto unrecorded malady. *Am J psychiatry.* 1849;6(2):97–127. doi: 10.1176/ajp.6.2.97.)

Telegram: @medical_k

www.konkur.in

That the psychiatric hospital played a far greater role than just treating acutely ill insane persons and restoring them to health was quite clear by that time. William Awl, superintendent of the Ohio Lunatic Asylum in Columbus, wrote in 1849:

More effort and skill is often demanded, to better the condition and make some improvement in the shattered intellects of those who are deemed hopeless, than to effect recoveries. . . We must never permit ourselves to lose sight of humanity, but always remember the importance of the institution to all classes, and the advantages which may be secured to those whom we are obliged to regard as incurable.

Thomas Kirkbride expanded on this note in 1864, indicating the importance of the safety function played by the hospital:

Owing to various causes, but especially to a neglect of treatment in the early stages of the disease, there are a large number of the insane, in every community, whose chances of restoration are slight, but whose comfort and happiness are promoted, and their protection from ill treatment secured by a residence in these institutions, where they are under circumstances which give them the best chance for permanent improvement. To provide for this numerous class is another important object, attained by the establishment of such hospitals. Next to these come the protection of the community and the relief of private families.

These roles quickly became compromised by the services being overwhelmed by the number of patients needing to be served. By 1890, W. W. Godding, the APA's seventeenth president, was observing:

The overcrowding goes on, cots are brought out at night and laid down on the corridor floors, at first one or two in nooks and alcoves that seem quite designed for this sort of thing, but the business grows, the special adaptation of recesses and alcoves becomes less apparent as the line of beds side by side stretches in lengthening vista down the hall. And still the floors fill up until one, two, three hundred are thus nightly not accommodated but provided for. From ground floor to attic your hospital, spread with its white beds seems a very bivouac of lunatics . . . Day by day, year after year, I have seen the individualized treatment of special cases swamped by the rising tide of indiscriminate lunacy pouring through the wards, filling every crevice, rising higher and higher until gradually most distinctions and landmarks have been blotted out. (Godding WW. Aspects and outlook of insanity in America. *Am J Psychiatry.* 1890;47(1):1–16.)

These trends persisted, such that by 1954 Kenneth Appel, the eighty-second president of the APA, echoed Godding:

There is overcrowding 20–30% in 70% of…hospitals, and 50% overcrowding in 8% of the hospitals. Hospitals are 40% understaffed in physicians; 15,000 more psychiatrists are needed; 37,000 patients in 29 hospitals have no psychiatrists, and 2,000 patients are in 5 hospitals which do not employ a full-time physician. (Appel KE. President's page. *Am J Psychiatry.* 1954;110(11):859–864. https://doi.org/10.1176/ajp.110.11.859)

Telegram: @medical_k

www.konkur.in

Four years later, Harry Solomon, director of the Boston Psychopathic Hospital, proclaimed:

> After 114 years of effort, in this year 1958, rarely has a state hospital an adequate staff as measured against the minimum standards set by our Association . . . I believe therefore that our large mental hospitals should be liquidated as rapidly as can be done in an orderly and progressive fashion.

Clinical concerns fueled the changing role of the hospital and the changing role of various classes of psychiatric hospitals (state, county, private, general hospital), but clinical concerns were never separate from fiscal concerns. It has never been clear which has been the predominant concern, but there is ample evidence accumulated over the last 150 years that economic considerations have been of no less importance than clinical considerations in defining the role of the hospital.

Social Control Rationale

Every state has statutes that govern the admission of persons with mental illness, over their objection, to hospitals within their state; the involuntary continued hospitalization of these individuals should they want to leave; the commitment of persons who have been charged with a crime and there is a question of their competency to stand trial and/or their criminal responsibility; and the transfer of inmates from jail and prisons to hospitals. Every state sets forth criteria under which an individual can be held on emergency detention and then civilly committed, and these criteria are uniformly danger to self, danger to others, and some variant of gravely disabled. The statutes for civil commitment are generally uniformly applied across hospital types, while forensic commitments are to government-run hospitals or in a few states to nongovernment hospitals with contracts with the state to provide such services.

In no other field of medicine could a competent person be admitted to a hospital over his objection. This occurs only in psychiatry and is the component of psychiatry that is social control. This social control function is the most fractious aspect of hospital psychiatry. It is this aspect of psychiatric hospitals that has been the brunt of antipsychiatry movements, whether they originate with psychiatrists themselves, for example, Thomas Szasz, R.D. Laing; religious groups; or individuals who label themselves “consumer survivors.”

So engulfing had the social control function of the psychiatric hospital become that until the early 1980s, simply being an involuntary patient at a

Telegram: @medical_k

www.konkur.in

psychiatric hospital meant one could be involuntarily medicated. The argument was a simple one: what was the purpose of holding a person in a hospital against his will if you could not treat him? This changed when, through litigation, the point was made that commitment is based on dangerousness, while the right to refuse treatment is based on competency (see, e.g., *Rogers v. Commissioner of Mental Health*, 390 Mass.489, 458 N.E.2d 308 [1982]).

The objection to the social control function of the hospital is hardly new. One-hundred and seventy-five years ago, Elizabeth Stone protested her admission to the McLean Asylum; 150 years ago, Elizabeth Packard made a career out of her protestations; and 70 years ago, actress Frances Farmer tried to rally the nation to support her self-proclaimed unjust involuntary admissions and treatment.

This week, in every state in the United States, there are individuals in various stages of civil and criminal commitment. There are also individuals being medicated over their objections. And what some believe is a glorious evolutionary step forward in mental health services and others think is a malevolent regression, a progressively larger percentage of involuntary treatment is taking place outside of hospitals, through AOT, mental health courts, conditional release, representative payeeships, leveraged housing, and probation.

So entrenched have these competing interests of social control versus autonomy become that each has its own set of slogans. Those in favor of treatment over objection in a defined set of circumstances talk about “rotting with your rights on.” Those in favor of free choice, no matter what the circumstances, chant: “Nothing about us without us.”

There is one area where both sides together object to the use of the psychiatric hospital as a social control agent—for individuals who do not meet the criteria for having a mental illness, or whose danger is not on the basis of a mental illness, or who are stuck in a hospital because they have no place to go—yet are committed to the psychiatric hospital. All states have their population of individuals who are there because their psychopathic behaviors land them in hospitals; individuals whose high-profile crimes make them “political prisoners,” and individuals whose dangerous sexual behaviors means they must be locked up somewhere. The latter situation is the basis for the Supreme Court decision in Kansas v. Hendricks (see Table 56.3–2).

Telegram: @medical_k

www.konkur.in

It is perhaps the irony of the social control function of psychiatric hospitals that law enforcement cannot get individuals into hospitals who need to be there because district attorneys, forensic review boards, families, and victims fight to keep individuals in psychiatric hospitals who do not need to be there. The social control function is highly susceptible to stigma and prejudice.

Fiscal Rationale

In 1912, there was a debate in Congress on a government health insurance program. President Franklin Roosevelt almost established a federal health plan as part of the 1935 Social Security Act. Presidents Harry Truman and John Kennedy had health care proposals before Medicare and Medicaid passed during President Lyndon Johnson's term in office. However, before all that, President Franklin Pierce played a major role in the early eschewal of federal responsibility for the health care of persons with mental illness.

The individual most responsible for bringing the issue to President Pierce's desk was Dorothea Dix, a well-known reformer. On June 23, 1848, Dix delivered a Memorial Lecture to the U.S. Congress. Dix's subjects, as stated in her address, were as follows: "Allowing at the present time 22,000,000 inhabitants in the United States and supposing only one in every thousand to be insane or idiotic, we have then 22,000 to take charge of." She described the state they were in:

> a majority of whom are in needy or necessitous circumstances . . . destitute of appropriate care and protection . . . bound with galling chains, bowed beneath fetters and heavy iron balls, attached to drag chains, lacerated with ropes, scourged with rods, and terrified beneath storms of profane execrations and cruel blows . . . abandoned to the most loathsome necessities, or subject to the vilest and most outrageous violations.

Dix's remedy was hospitals: "No disease is more manageable or more easily cured than insanity; but to this end special appliances are necessary, which cannot be had in private families, nor in every town and city; hence the necessity for hospitals." Dix appealed to the legislators' sense of doing what is right: "Humanity requires that every insane person should receive the care appropriate to his condition." She articulated the social control function of the hospital by spelling out the civil and social obligation to consult and secure the public welfare: "First, in affording protection against the frequently manifested dangerous propensities of the insane." Furthermore, she made a powerful economic argument,

Telegram: @medical_k

www.konkur.in

indicating the insane and the community at large would benefit by "assuring seasonable and skillful remedial care, procuring their restoration to usefulness as citizens of the republic, and as members of communities."

Edward Jarvis best articulated the 19th-century position on the cost of care versus the cost of treatment that was fundamental to Dix's campaign:

> A man of twenty years of age, if sane, has an average life of 39.48 years, while if insane he has but an average life of 21.31 years if not restored to health. The average time for restoring to health the insane who apply for treatment upon the early symptoms of disease is twenty-six weeks. At $4 per week, which was the average cost in the three State Lunatic Asylums in Massachusetts for the past year, this amounts to $104, to which is added $30 for each patient, for the cost of rent or interest on the value of the hospital, etc., for six months, making an average cost of $134 for restoration to health. If not restored to health, the family or State must be at an expense of $156 a year for 21.31 years, and must also lose the patient's earnings for the 39.48 years which he would have made if well. The cost of the patient's support is estimated at $2,121, while the loss of his future labor, if he becomes insane at twenty years of age, is estimated at $2,665.37, making a total loss of $4,786.37 if not cured; while, if cured in the average time of twenty-six weeks at a cost of $134, there will be a gain to the family or to the State of $4,652. (Jarvis E. Treatment of insanity. In: Mann EC, ed. *A Manual of Psychological Medicine and Allied Nervous Diseases.* P. Blakiston, Son & Co; 1883.)

Dix lobbied for her land grants bill through four presidential administrations. The bill was passed by both houses of Congress during Franklin Pierce's term. However, Pierce vetoed the bill. In his Veto Message on May 3, 1854, first, he laid out the issues as he saw them:

> It cannot be questioned that if Congress has power to make provision for the indigent insane without the limits of the District it has the same power to provide for the indigent who are not insane, and thus to transfer to the Federal Government the charge of all the poor in all the States. It has the same power to provide hospitals and other local establishments for the care and cure of every species of human infirmity . . . The whole field of public beneficence is thrown open to the care and culture of the Federal Government.

Later in his Message, he explained the basis for his veto:

> If the several States, many of which have already laid the foundation of munificent establishments of local beneficence, and nearly all of which are proceeding to establish them, shall be led to suppose, as, should this bill become a law, they will be, that Congress is to make provisions for such objects, the fountains of charity will be dried up at home, and the several States, instead of bestowing their own means on the social wants of their own people, may themselves, through the strong temptation which appeals to states as to individuals, become humble supplicants for the bounty of the Federal Government.

Telegram: @medical_k

www.konkur.in

From the veto by President Pierce into the early decades of the 20th century, the federal government was basically disinterested in the psychiatric and substance abuse populations. It eventually turned to the issues around the treatment of this population due to concerns about drug addiction. In 1914, the Harrison Narcotics Act allocated funds to study drug use. Subsequently, the Narcotics Division within the U.S. Public Health Service was created. It was renamed 2 years later the Division of Mental Health. In 1996, the federal government focused on mental illness with the passage of the National Mental Health Act, which established the National Institute of Mental Health (NIMH).

In 1989, the Omnibus Budget Reconciliation Act (OBRA) required the secretary of the Department of Health and Human Services to conduct a study of the IMD exclusion. The IMD exclusion dated from the 1950 Social Security Act Amendments, in which payments on behalf of those in IMDs were excluded from old-age assistance. This exclusion continued unchanged until the enactment of Medicaid under the Social Security Act Amendments of 1965. For the first time, states could use Federal Financial Participation (FFP) for a population in IMDs—in this case, those 65 years of age or older. States could bill the federal government to help pay for the treatment in psychiatric hospitals of patients who were older than the age of 65 years. Other populations were not included, but Congress did expand FFP for services to persons with mental illness in general hospitals.

The 1965 changes to the IMD exclusion began to allow states to shift the cost of mental illness expenditures to the federal government. In a state hospital, the state bears 100% of the cost of care and treatment. The state cannot bill Medicaid. In any facility that is eligible for Medicaid reimbursement, each state pays considerably less than 100%, according to the FFP formula: Nonfederal percentage = 45% × (per capita state income) ÷ (per capita national income). Historically the range of federal participation has been between 50% and 83%—thus the fiscal incentive to move patients out of state hospitals.

An IMD is a facility with more than 16 beds. In addition, any one of the following defines an IMD: (1) the facility is licensed as a psychiatric facility, (2) the facility is accredited as a psychiatric facility, (3) the facility is under the jurisdiction of the SMHA, (4) the facility specializes in providing psychiatric/psychological care and treatment, or (5) the current need for

Telegram: @medical_k

www.konkur.in

institutionalization for more than 50% of all of the patients/residents in the facility results from mental diseases.

In 1971, Congress expanded Medicaid to include coverage of services rendered in intermediate care facilities (ICFs). In 1972, Congress expanded FFP for inpatient psychiatric treatment in IMDs to individuals younger than 21 years of age so that now those younger than 21 and older than 65 years of age are eligible.

The IMD exclusion sets up a tension between the states and the federal government, each wanting to lower its share of the costs for psychiatric hospital treatment. Between 1972 and 1988, the federal government was busy with evaluating the proper application of the IMD exclusion by the states, disallowing certain states' practices, and defending itself in court. This culminated in the 1985 U.S. Supreme Court decision in *State of Connecticut Department of Income Maintenance v. Heckler,* in which the Court unanimously found for the federal government, indicating that a hospital, a skilled nursing facility (SNF), or an ICF could be an IMD.

Thus, the IMD exclusion profoundly affects the role of the psychiatric hospital and the distribution of patients across types of hospitals. States would rather have persons with mental illness in community residential settings than in state hospitals and in general hospitals rather than state hospitals. In both situations, the former means Medicaid payments; the latter means no Medicaid reimbursement.

No matter what the sector or who the payer, however, in the last quarter of the 20th century, inpatient psychiatric treatment was getting more and more costly—hence the rise of managed care. Starting in the 1970s and continuing through the early 1980s, the principal methods for cost containment were actuarial manipulations designed to manage benefits. There was little regard for the effect these changes in benefits had on the indirect costs borne by beneficiaries, employers, and/or the community. Changes were made without consideration of their effects on the displacement of care onto the general medical sector. Modifications in benefit plan design included the imposition of restrictions, exclusions, limitations, and penalties; provision of incentives; requirements for prior authorization; and retrospective denial of claims. This methodology is managing benefits.

Managing benefits changed into cost control through management of care, a methodology claimed to be more patient-focused. By limiting authorization of expenditures to only those services deemed medically

Telegram: @medical_k

www.konkur.in

necessary and appropriate, delivered in the least restrictive and least intrusive treatment settings, and only by previously designated qualified practitioners, advocates of managed mental health care believed that proper care could be delivered to patients at the appropriate times, in designated settings, by the right type of provider, in skillfully titrated amounts, and at considerable cost savings. Techniques used to achieve this end included management through contracting, profiling, credentialing, and educating hospitals; organizing hospitals into a specialized, accessible, and interactive network of behavioral health care providers; using mandated standardized pretreatment assessment and treatment planning methods; and requiring the use of standardized forms, restricted formularies, and outcomes management.

Though not yet achieved, the more progressive goals of managed behavioral health care are disease management, demand reduction, health promotion, and wellness. Health maintenance organizations (HMOs) and other capitation-based arrangements have fiscal incentives to use these strategies, but both efforts and results have yet to be really impressive. Nonetheless, the techniques used mean that managed care has and continues fundamentally to affect the role of the psychiatric hospital.

The federal government sought further cost containment. The Tax Equity and Fiscal Responsibility Act of 1982 (TEFRA) led to new methods to control Medicare costs, the most significant being diagnostic-related groups (DRGs) for reimbursement. With the end of cost-plus reimbursement and its replacement with reimbursement based on diagnosis, hospital profits for medical and surgical treatment began to decline. The behavioral health care industry was initially unaffected by DRGs, largely because psychiatric diagnoses were thought to lack sufficient power to predict the course of treatment. Thus, there appeared to be tremendous financial opportunities available in the relatively unregulated behavioral health care market. These opportunities were short-lived; the rise and fall of for-profit psychiatric hospitals were equally steep, as described earlier. With the application of DRGs to psychiatry, this fiscal advantage also dissipated. Thus, the federal government, through Medicare and Medicaid, fundamentally affects the role of the psychiatric hospital.

Although the modern era of managed behavioral health care began in the private sector, these principles and practices spread to the public

Telegram: @medical_k

www.konkur.in

sector. Medicaid Managed Care was initiated due to the spiraling costs of the Medicaid program. Between 1985 and 1993, Medicaid costs tripled, and the number of beneficiaries increased by more than 50%.

Other Governmental Considerations

Although state governments most directly affect the roles of psychiatric hospitals—through state laws, regulations, licensure, inspections, and investigations—the federal government has profoundly changed the roles of psychiatric hospitals through federal legislation and court decisions. Table 56.3–2 provides a summary of these influences over the last six decades.

The federal government's influence can be examined through the example of the right to treatment. Much of the right-to-treatment litigation has focused on establishing standards of care and concomitant staffing patterns. In the 1940s, the APA maintained there should be no less than 1 psychiatrist for every 150 hospitalized patients, 1 graduate nurse for every 40 patients, and 1 attendant for every 8 patients. No state hospital of the day met all of the APA's standards.

The right to treatment was initially articulated by Morton Birnbaum, a lawyer, and physician in 1960. There followed a series of lower-court cases: *Lake v. Cameron* (1966), *Rouse v. Cameron* (1966), *Nason v. Superintendent of Bridgewater State Hospital* (1968), *Wyatt v. Stickney* (1971), and *New York State Association for Retarded Children v. Rockefeller* (1973), the so-called Willowbrook case. Each of these is briefly explained in Table 56.3–2.

The U.S. Supreme Court decided three cases between 1975 and 1982 that might have established a right to treatment, meaning states that would be obligated to treat committed patients. In *O'Connor v. Donaldson* (1975), the Court found "A State cannot constitutionally confine, without more, a nondangerous individual who is capable of surviving safely in freedom by himself or with the help of willing and responsible family members or friends." In *Halderman v. Pennhurst State School & Hospital* (1977), the Court again did not reach the issue of a constitutional basis for a right to treatment or habilitation. In *Youngberg v. Romeo* (1982), the Court went the furthest it has to date when it held that persons with mental retardation who were involuntarily committed to institutions have "constitutionally protected liberty interests under the Due Process Clause of the Fourteenth Amendment to reasonably safe conditions of

Telegram: @medical_k

www.konkur.in

confinement, freedom from unreasonable bodily restraints, and such minimally adequate training as reasonably may be required by their interests." Had the Supreme Court established a right to treatment, the roles of psychiatric hospitals might have been considerably expanded.

The major advances in the right to treatment in the 1980s occurred pursuant to the Civil Rights of Institutionalized Persons Act (CRIPA) of 1980. This act authorized the U.S. government to institute a civil action against any state whose officials, employees, or those acting on their behalf are "subjecting persons residing in or confined to an institution to egregious or flagrant conditions which deprive such persons of any rights, privileges, or immunities secured or protected by the Constitution or laws of the United States causing such persons to suffer grievous harm." Under this authority, the Civil Rights Division of the U.S. Justice Department has been able to substantially bring the right to treatment closer to a reality for thousands of persons in a state, county, or municipal psychiatric hospitals by applying the standards of *Youngberg* to negotiate consent decrees. A consent decree is a document filed with the court in which the two parties sign a binding agreement in lieu of litigation.

Table 56.3–2.
Federal Government and Court Actions Defining the Role of Hospital Treatment Over the Last Six Decades

Telegram: @medical_k

www.konkur.in

1955	The Mental Health Study Act of 1955 (Public Law 182) calls for a nationwide analysis and re-evaluation of the human and economic problems of mental illness. It leads to the formation of the Joint Commission on Mental Illness and Health.
1963	President John Kennedy submits to Congress a “Special Message on Mental Illness and Mental Retardation” that calls for a “wholly new national approach” to those two health problems.
1960	In *Dusky v. United States,* U.S. Supreme Court affirmed a criminal defendant’s constitutional right to have a competency evaluation before proceeding to trial and setting the standard for determination of such competence. This has subsequently meant many individuals are sent to state hospitals every year for competency evaluations.
1964	*Dixon v. Weinberger*, filed in U.S. District Court of the District of Columbia, claims that patients at St. Elizabeth’s Hospital have a statutory right to treatment and that those involuntarily committed under the 1964 Hospitalization of the Mentally Ill Act of the District of Columbia must be placed in the least restrictive setting consistent with suitable treatment.
1965	Medicare legislation is passed. It includes limited coverage for patients receiving active treatment in state hospitals in addition to those in general hospitals.
1966	The Social Security Amendments of 1965 (Public Law 89–97) adds Title XIX, Medicaid, to the Social Security Act. Medicaid funds psychiatric treatment in general hospitals for those under categorical assistance programs and who qualify as medical indigents, and it improves coverage for psychiatric illness under Medicare.
	In *Lake v. Cameron*, a U.S. court of appeals rules that an individual could not be committed to the hospital until

Telegram: @medical_k

www.konkur.in

hospital officials determined that there was no less-restrictive facility available to care for her.

In *Rouse v. Cameron*, a U.S. court of appeals finds that a criminal defendant who is acquitted by reason of insanity and involuntarily committed to a psychiatric hospital has a right, legally enforceable through habeas corpus, to adequate and suitable treatment.

1970 *Wyatt v. Stickney* is filed in federal district court in Alabama, addressing the issue of detention without treatment of involuntarily civilly committed persons. The court subsequently finds that three fundamental conditions are necessary for adequate and effective treatment in public psychiatric hospitals: A humane psychological and physical environment, enough qualified staff to administer adequate treatment, and individualized treatment plans.

1972 In *Lessard v. Schmidt*, a federal district court decides that under the due process provisions of the Constitution, persons facing involuntary civil commitment are guaranteed the full array of procedural safeguards formerly guaranteed only to individuals charged with a crime.

1973 In *Souder v. Brennan*, a federal district court finds that patient–workers are covered by the Federal Fair Labor Standards Act, entitling them to minimum wages and overtime compensation.

1974 In *Donaldson v. O'Connor*, the U.S. Fifth Circuit Court of Appeals rules that a person who is involuntarily civilly committed to a psychiatric hospital has a constitutional right "to such treatment as will help him be cured or to improve his mental condition." The U.S. Supreme Court issues its decision in this case on June 26, 1975, finding that "a State cannot constitutionally confine, without more, a nondangerous individual who is capable of surviving safely in freedom by himself or with the help of willing and responsible family members or friends."

Telegram: @medical_k

www.konkur.in

1975 The first class-action suit on the right to refuse treatment is filed for Boston State Hospital patients in a case originally known as *Rogers v. Okin* (right-to-refuse-treatment cases were basically decided on state-by-state basis to the end of the century, with very different rulings among the states).

1975 In *Drope v. Missouri*, the U.S. Supreme Court rules when deciding whether to evaluate a criminal defendant's competency, the court must consider any evidence suggestive of mental illness, even one factor alone in some circumstances. Therefore, the threshold for obtaining a competency evaluation is low. When the issue is raised, the motion should be granted. This means even more individuals sent to the state hospital for evaluation.

1976 In *Tarasoff v. Regents of the University of California*, the California Supreme Court rules that "when a therapist determines, or pursuant to the standards of his profession should determine, that his patient presents a serious danger of violence to another, he incurs an obligation to use reasonable care to protect the intended victim against such danger."

1978 In *Rennie v. Klein*, the U.S. Supreme Court rules that an involuntarily committed, legally competent patient who refuses medication has a right to professional medical review of the treating psychiatrist's decision. The Court left the decision-making process to medical professionals. This decision changed the long-standing practice whereby a committed patient could be treated over his object simply because he had been committed.

1979 In *Addington v. Texas,* the U.S. Supreme Court holds that the standard of proof in civil commitment hearings is "clear and convincing," a lower standard than "beyond a reasonable doubt."

1980 The Civil Rights of Institutionalized Persons Act allows the federal government to initiate actions against states whose public institutions, such as hospitals, prisons,

Telegram: @medical_k

www.konkur.in

nursing homes, and jails, deny residents their constitutional rights.

In *Suzuki v. Yuen,* the U.S. Court of Appeals for the Ninth Circuit rules that involuntary civil commitment solely on the grounds of danger to property is unconstitutional.

1981 In a 5-to-4 decision, the U.S. Supreme Court rules that inpatients of public psychiatric institutions are not eligible for Supplemental Security Income (SSI) payments granted to mentally ill patients in other settings.

1982 In *Youngberg v. Romeo*, the U.S. Supreme Court decides that a person in an institution has a constitutionally guaranteed "right to personal security," "a right to freedom from bodily restraint," and the right to receive "such training as an appropriate professional would consider reasonable to ensure his safety and to facilitate his ability to function free from bodily restraints."

Congress enacts the Tax Equity and Fiscal Responsibility Act (Public Law 97–248), which sets the stage for a prospective payment system for Medicare.

1985 In *Ake v. Oklahoma,* the U.S. Supreme Court rules indigent criminal defendants have a right to a competency evaluation. The potential pool of persons who can be sent to state hospitals for evaluation expands again.

1990 The Americans with Disabilities Act (ADA) is enacted to eliminate discrimination against disabled persons. Title II says, "No qualified individual with a disability, shall, by reason of such disability, be excluded from participation in or be denied the benefits of the services, programs, or activities of a public entity, or be subjected to discrimination by any such entity."

1991 The Patient Self-Determination Act, a part of the Omnibus Budget and Reconciliation Act of 1990, requires health care facilities that receive Medicare and Medicaid

Telegram: @medical_k

www.konkur.in

funding to provide information to adult patients about their right to make their own health care decisions, including the right to accept or refuse treatment and to execute advance directives about medical care.

1997 In *Kansas v. Hendricks*, the U.S. Supreme Court rules that sex offenders can be civilly committed because they "suffer from a volitional impairment rendering them dangerous beyond their control" and because "far from any premature objection, the confinement's duration is instead linked to the stated purpose of the commitment, namely to hold the person until his mental abnormality no longer causes him to be a threat to others."

1999 In *Olmstead v. L.C. and E.W.*, the U.S. Supreme Court rules that the ADA requires states to provide community placement for persons with mental disabilities if the state's treatment professionals have determined it is appropriate, if it is not opposed by the individuals affected, and if it can be reasonably be provided considering state resources and the needs of other disabled persons.

Publication of *Mental Health: A Report of the Surgeon General.*

2000 The Ticket to Work and Work Incentives Improvement Act permits states to increase the level of income disabled persons can earn before they become ineligible for Medicaid and extends the period that disabled persons can be employed and the income they can earn before losing Medicare coverage.

Wyatt v. Sawyer (formerly *Wyatt v. Stickney*) settled.

The Drug Addiction Treatment Act allows office-based heroin treatment by permitting qualified physicians to prescribe take-home doses of buprenorphine.

Federal legislation authorizes $10 million over 4 years to establish up to 100 mental health courts.

Federal rules are issued establishing a national uniform standard for protecting the privacy of medical records.

Telegram: @medical_k

www.konkur.in

2001	The Surgeon General promulgates a national strategy for suicide prevention: *National Strategy for Suicide Prevention: Goals and Objectives.*
	The Health Care Financing Administration is restructured and renamed the Center for Medicare and Medicaid Services (CMS).
2002	The Department of Health and Human Services releases *Report to Congress on the Prevention and Treatment of Co-occurring Substance Abuse and Mental Disorders*.
2003	The President's New Freedom Commission on Mental Health puts out its report, *Achieving the Promise: Transforming Mental Health Care in America*.
2004	A federal district court in Oregon requires the state to eliminate a $250 copayment for hospital visits for the standard population of the Oregon Health Plan.
2005	The federal government, jointly through the Department of Health and Human Services (DHHS), the Department of Housing and Urban Development, the Department of Justice, the Labor Department, the Veterans Administration, and the Social Security Administration, put out *Transforming Mental Health Care in America. The Federal Action Agenda: First Steps*. This starts a multiyear venture to alter the forms and functions of the mental health system in the United States.
2006	The 2006 Budget Reconciliation Act alters Medicaid rules, such that states can impose premiums and higher cost sharing on beneficiaries, as well as allows states to provide scaled-back Medicaid benefit packages. One consequence is transferring some Medicaid beneficiaries to the rolls of the uninsured, with hospitalization going from Medicaid reimbursement to free care.
	The Substance Abuse and Mental Health Services Administration (SAMHSA) provides a training curriculum to reduce (or eliminate) the use of seclusion and

Telegram: @medical_k

www.konkur.in

restraint: *Roadmap to Seclusion and Restraint Free Mental Health Services*.

The CMS publishes final rules on the use of seclusion and restraint in the *Federal Register*. The new limits (previously there were none) are: Adults, 4 hours; children and adolescents age 9–17 years, 2 hours; and children younger than age 9 years, 1 hour.

Implementation of Medicare Part D.

2007 The Agency for Healthcare Research and Quality (AHRQ) of the DHHS reports that there is no evidence base for the off-label use of atypical antipsychotics.

SAMHSA, in *An Action Plan for Behavioral Workforce Development*, reports “an anemic pipeline of new recruits to meet the complex behavioral health needs of the growing and increasingly diverse population in this country.”

The AHRQ, in *Care of Adults with Mental Health and Substance Abuse*, reports that 6% of all community hospital stays were primarily for psychiatric or substance use disorders and nearly 25% included such a disorder.

Federal judges in Wisconsin question diagnoses invented to civilly commit sex offenders after expiration of their criminal sentence. In *Brown v. Watters* the diagnosis was “paraphilia not otherwise specified-nonconsent”; in *McGee v. Bartow* the diagnosis was “personality disorder not otherwise specified with antisocial feature.” Neither is a *Diagnostic and Statistical Manual of Mental Disorders*, fourth edition (DSM-IV) diagnosis.

2008 The Paul Wellstone and Pete Domenici Mental Health Parity and Addiction Equity Act of 2008 (MHPAEA) amended the Public Health Service Act, the Employee Retirement Income Security Act (ERISA) and the Internal Revenue Code, to require group health plans and health insurance issuers to ensure that financial requirements (such as copays, deductibles) and

Telegram: @medical_k

www.konkur.in

	treatment limitations (such as visit limits) applicable to mental health or substance use disorder benefits are no more restrictive than the predominant requirements or limitations applied to substantially all medical and surgical benefits.
2010	The Affordable Care Act was passed by Congress and then signed into law by President Obama on March 23, 2010. Titles I. Quality, Affordable Health Care for All Americans and II. The Role of Public Programs and V. Health Care Workforce have direct impact on psychiatric hospitals.
2012	U.S. Supreme Court rules in *National Federation of Independent Business v. Sebelius*on June 28, 2012, in a 5–4 ruling, that the Affordable Care Act is constitutional. The court defines the individual mandate as a tax and not a mandate and provides a choice for States to Opt-Out of Medicaid Expansion.
2013	A final regulation implementing MHPAEA is published in the Federal Register on November 13, 2013.
2013	Representative Tim Murphy (R-PA) introduces, on December 12, 2013, H.R.3717—Helping Families in Mental Health Crisis Act of 2013 which is the first comprehensive federal legislation addressing the needs of those with serious mental illness since President Kennedy's Community Mental Health Act in 1963.
2014	Representative Ron Barber (D-AZ) introduces, on May 2, 2014, H.R. 4574—The Strengthening Mental Health in Our Communities Act, the House Democrats' alternative to the bill filed by representative Murphy.
2014	U.S. Supreme Court Justice Ruth Bader Ginsburg files a dissenting opinion in *Burwell v. Hobby Lobby Stores, Inc.*, a decision that exempts employers from covering birth control (as required by the Affordable Care Act) if the employer objects on religious grounds. One of Ginsburg's queries was, could Scientologist employers not cover antidepressants on religious grounds?

Telegram: @medical_k

www.konkur.in

2014	On April 1, 2014, President Obama signed into law the Protecting Access to Medicare Act (H.R. 4302), which includes a demonstration program based on the Excellence in Mental Health Act. This act (1) creates criteria for "Certified Community Behavioral Health Clinics," (2) provides $25 million that will be available to states as planning grants to develop applications to participate in the 2-year pilot, (3) stipulates that 8 states will be selected to participate in the 2-year pilot program, and (4) requires participating states to develop a Prospective Payment System for reimbursing Certified Behavioral Health Clinics for required services they provide.

On July 26, 1990, the Americans with Disabilities Act (ADA) passed and established a "clear and comprehensive prohibition of discrimination on the basis of disability." Title II is of greatest interest because this title covers state and local government services, and so includes public hospitals. Title II indicates "no qualified individual with a disability shall, by reason of such disability, be excluded from participation in or be denied the benefits of the services, programs, or activities of a public entity, or be subject to discrimination by any such entity." One regulation promulgated to operationalize this Act states, "A public entity shall administer services, programs, and activities in the most integrated setting appropriate to the needs of qualified individuals with disabilities." This marks a shift from the long-standing standard, "least restrictive alternative," to the new standard, "most integrated setting." The ADA was seen not so much as a way to improve services within hospitals as a way to force states to move patients out of these institutions.

The hallmark Supreme Court decision to date applying the ADA to persons in hospitals is *Olmstead v. L.C.* (1999). The case involved two women who were in a Georgia state hospital despite the fact that treatment professionals had concluded each could be appropriately treated in community-based programs. The Court found that the "unjustified isolation . . . [of persons with mental disabilities] is properly regarded as discrimination based on disability." The basis for this finding was that "Institutional placement of persons who can handle and benefit from community settings perpetuates unwarranted assumptions that

Telegram: @medical_k

www.konkur.in

persons so isolated are incapable or unworthy of participating in community life." The justices then made a leap to the conclusion that institutional confinement "severely diminishes the everyday life activities of individuals, including family relations, social contacts, work options, economic independence, educational advancement, and cultural enrichment." Thus, began the most recent wave of translocating persons from a public psychiatric hospital to alternative settings. Apparently, general hospitals and private hospitals were deemed "in the community." So too, based on the most recent data, are jails and prisons.

FULFILLING THE ROLE

The hospital fulfills its role in the care and treatment of psychiatric patients in a prescribed way. Efficacious treatment derives from effectively performing each step.

Assessment

Assessments are done by individual practitioners of different disciplines. An admission assessment is conducted by a physician, preferably a psychiatrist. This assessment, done at the patient's presentation to the hospital, documents the chief complaint; the basis for admission and history of the present illness; relevant past psychiatric history, family history, and social history; a complete mental status examination; a substance abuse screen; and a risk assessment (suicide, homicide, fire setting, others). This assessment should lead either to admission or to nonadmission with an outpatient plan.

A nursing assessment is completed as soon after the patient's arrival on the ward as possible, but no later than 8 hours. The nursing assessment overlaps in part with the physician admission assessment but covers some areas in less detail and others in more detail. The nursing assessment includes a pain assessment, a falls risk assessment, skin care concerns, and special nursing care needs.

The third assessment that needs to be completed proximate with admission is the medical history and physical examination. This is done either by the admitting psychiatrist or by an internist, depending on the staffing of the hospital. Besides attending to general medical history, particular attention needs to be paid to how medical disorders and physical findings might be affecting the psychiatric presentation.

Telegram: @medical_k

www.konkur.in

All three of these assessments need to cover the areas of alcohol and substance use/abuse. Positive screens lead to an alcohol and drug abuse assessment, preferably completed by staff with expertise in this area.

Other disciplines need to complete their assessments prior to the interdisciplinary team (IDT) meeting at which the Treatment and Recovery Plan (TRP) is developed. These assessments include those by social work—the psychosocial assessment—and by rehabilitation services (often inappropriately referred to as “activities therapy”). The psychosocial assessment needs to provide information from collateral sources when such information is necessary to complete the database, there are collateral sources to contact, and the patient has provided permission (release of information) to contact specific individuals. Some hospitals include a psychology assessment on all admission; others use psychologists who function as consultants, and psychological assessments are conducted only on referral. Dietician assessments are often done routinely; medical specialty assessments are done on referral.

Formulation

Traditionally, the weakest part of the process is from assessment to intervention, and one is often left out entirely. The formulation needs to be seen as a fundamental part of the process. The formulation pulls the data together into a coherent picture of the individual. It is not a brief restatement of the facts of the case. The formulation takes the symptoms, which are the basis for an understanding of the *patient*, and adds significant historical information to provide an understanding of the *person*.

Leaving out or improperly constructing the formulation leads to the loss of important information that does not directly translate into diagnoses but is crucial for effective treatment planning. Formulations may be recorded as components of each assessment—for example, psychiatric formulation, nursing formulation—and then brought together at the IDT meeting, or they may be written at the IDT meeting by the psychiatrist drawing from all of the assessments.

Treatment Planning

Because treatment must commence at the onset of hospitalization, the Initial Treatment and Recovery Plan (ITRP) is, of necessity, a multidisciplinary process. The ITRP is initiated by the admitting

Telegram: @medical_k

www.konkur.in

psychiatrist and nurse based on their assessments. Other disciplines add to the ITP as they conclude their assessments.

Whereas the ITRP provides the basis for directing treatment during the first few days of hospitalization, the rationales for specific interventions must be included in either the assessments or in the progress notes. For example, each medication ordered by the admitting physician must have a documented rationale. It is not sufficient simply to state that medications taken prior to admission are being continued because this does not provide any basis for the medications. Stating that aripiprazole and clozapine, for instance, are being prescribed fails to justify polypharmacy without providing a basis beyond recording that these were the medications prescribed by the CMHC psychiatrist. Furthermore, any as-needed (PRN) medication ordered at admission needs to have a rationale, one that is specific to the patient. Ordering lorazepam 2 mg orally for agitation and haloperidol 5 mg orally for severe agitation is not sufficient. Such orders are neither specific to the patient nor do they inform the nurse what the prescriber means by “agitation” and what he means by “severe agitation.”

The TRP expands upon the ITRP and derives from an *interdisciplinary* process. The IDT is composed of professional and paraprofessional staff, as well as the patient. The patient, assisted by staff, is free to invite any other individuals to this meeting, for example, family members, friends, or advocates. The purpose of the IDT meeting is to *write* the TRP. It is not a time to sanction a TRP written before the meeting by one member of the IDT. The meeting uses multidisciplinary assessments as the basis to create an interdisciplinary treatment plan.

The creation of the TRP follows an orderly process. The IDT establishes, with the patient as the lead, the problems, which in the inpatient setting are predominantly barriers to discharge. Other problems may be addressed, depending on the expected length of stay of the patient. For each problem, there is a long-term goal (LTG) and a set of short-term goals (STGs) or objectives. The goals are the patient’s goals, not the staff’s goals for the patient. Hence, problems and goals belong to the patient. For each STG, there is a series of interventions. Interventions are what the staff does, not what the patient does. Each intervention under an STG must specifically assist the patient to move toward the achievement of that STG.

Telegram: @medical_k

www.konkur.in

STGs need to be specific, measurable, attainable, realistic, and timely (often referred to by the acronym SMART). STGs are intermediate steps toward the accomplishment of the LTG. Small steps that the patient reaches at intervals reinforce the patient and the staff.

Interventions need to specify the frequency of the intervention, the duration of the intervention, and the name of the intervener. For example, “Nurse Nightingale provides Medication Education Group, Tuesday and Thursday, 10:00–10:45 a.m.”

Common errors in interventions include the following:

1. Writing job descriptions: “Nurse Nightingale will administer medication and monitor for side effects.”
2. Failing to document intervener and/or duration: “Anger Management Group Wednesdays.”
3. Including interventions unrelated to the STG, such as “Dr. Woodward will meet with patient Mondays, 1:00–1:20 p.m. to review concerns about weight gain from clozapine,” when the STG is “Patient will have one five-minute telephone conversation per day with mother for three consecutive days without telling her mother to drop dead or piss off.”
4. Using terms that communicate no specific intervention (and can often be dangerous to staff if done wrong) such as “encourage patient to . . . ” or “assist patient to . . . ” If such interventions are used, the intervention must be explicit about how the “encourage” is to be done.

The ideal sets of interventions are clear, concise, and explicit. If the entire IDT were out sick one day, covering staff should be able to treat the patient by performing the interventions.

The TRP is the road map for the patient’s treatment. Active treatment—a concept or phrase used by many certifying entities—is defined as that treatment found as an intervention on the TRP that moves the patient toward the achievement of an STG that moves the patient toward the achievement of an LTG that addresses one of the patient’s problems. A simple rule when one is calculating active treatment hours for a patient is, “if it’s not on the treatment plan, it’s not active treatment.”

Progress is recorded in progress notes. These are written pointedly addressing STGs. Each note needs to be labeled with the discipline of the intervener and the STG being addressed. Thus, there would be no nursing staff note reading “Patient ate well and slept well” unless eating and sleeping were problems on the TRP with specific LTGs and STGs.

Telegram: @medical_k

www.konkur.in

The initial TRP is completed within a specified time frame, varying between 1 and 10 days, and specified by the facility's policies and procedures. The TRP is reviewed through IDT meetings at which treatment plan reviews (TRPRs) are conducted. The TRPR builds on the TRP, uses progress or lack thereof noted in the progress notes, and modifies the TRP as needed. TRPRs also occur on a schedule. In units with short lengths of stay, the TRPR occurs from daily to every 3 days. In intermediate length of stay units, TRPRs occur weekly for 60 days, then every 2 weeks for 60 days, then monthly. In longer stay units, TRPRs may occur monthly after the TRP done at 10 days.

Besides occurring on a scheduled basis, TRPRs need to occur in response to a patient's clinical need. Many hospitals have thresholds that, when met, require a TRPR to be held within one business day. Such thresholds included (1) any episode of seclusion or restraints; (2) a specific number of episodes of seclusion or restraint or a specific number of hours of seclusion or restraint within a designated time frame; (3) the administration of any psychiatric medication PRN or a given number of PRNs within a specified time frame; (4) the initiation of 1:1 observation; and/or (5) any serious incident, for example, patient-on-patient assault, patient-on-staff assault, or suicide attempt.

The TRP needs to be comprehensive or account for why it is not (either in the TRP or in the hospital's policies and procedures) in all but acute care settings. Thus, the TRP would be expected to address all of the patient's psychiatric and medical problems on longer-term units. A TRP could provide interventions for those problems that are impediments to discharge and address other problems as resources allow; this is often the case on intermediate-length-of-stay units. A CTP could address only those problems that are impediments to discharge with the expectation other problems will be addressed in treatment after discharge; such an approach is often employed on short-term units. This does not mean that maintenance treatments will not be provided for acute or chronic problems that are not the focus of the hospitalization, such as antihypertensive medications, treatments for gastroesophageal reflux disease or constipation, and hypnotic medications.

There is a new emphasis on tying the hospital TRP to a community TRP for persons with SMI in systems of care (traditionally CMHCs, but now also health homes and other integrated care settings). In the person-centered approach, the community TRP starts with the individual's "life

Telegram: @medical_k

www.konkur.in

goals." Community clinicians, support and outreach staff (peer and nonpeer workers), and naturalistic resources are channeled toward assisting the individual to move ever closer to his life goals. Hospitalization is usually a detour on the journey toward one's life goal, so focusing on problems that are impediments to discharge is in the service of returning the person to the community to take up the pursuit of his individualized life goals. To do so effectively, the hospital TRP should record the life goals as anchor points.

Treatment

Treatment planning is necessary but not sufficient for effective treatment to ensue. Members of the IDT plus other staff need to provide integrated treatment that follows the plan.

Psychopharmacologic treatment is a mainstay of contemporary inpatient treatment but must be prescribed (physician), dispensed (pharmacist), and administered (nurse) with awareness of contemporaneous interventions. Either initiating psychotropic medication or adjusting medication regimens is considered the sine qua non of inpatient psychiatry. Of course, not all admissions require medication, and distinguishing these patients from all others is an important function of the assessments and observations that are unique to the inpatient setting.

In prescribing medication, the attending psychiatrist must communicate the reasons for the medication and its side effects not only to the patient (obtaining informed consent before ordering the medication) but also to all members of the IDT. Hence, the importance of monitoring progress and informative progress notes accompanying each order.

PRN medications warrant particular attention. PRN medication transfers de facto prescription authority from physician to nurse because the nurse decides when and how much medication the patient will receive (within the parameters set by the physician). Unless the physician checks daily on the total dose of each PRN medication given, it is not possible for the physician to relate the patient's progress to the medication administered. Hospitals have taken various approaches to PRN psychotropic medication, including eliminating them entirely, limiting the orders to short-term orders, for example, 3 or 5 days, or allowing PRNs only on admission units and not on other units within the hospital.

Well-written progress notes by the psychiatrist assist the nurse in writing useful nursing progress notes. Writing "patient remained calm and

Telegram: @medical_k

www.konkur.in

cooperative throughout shift" may convey no useful information if, for example, the patient is depressed with a recent suicide attempt and is externally calm and cooperates because it takes less energy and concentration to do so than not to do so. A physician progress note detailing the specific target signs and symptoms for which antidepressant X has been prescribed provides the foundation for the nurse to write progress notes that focus on those signs and symptoms. If the physician simply writes antidepressant X for "dysphoria" or "depression," progress notes by other staff members are likely to be equally uninformative.

Another function shared predominantly by the psychiatrist, and the nursing staff (Registered Nurse [RN], Licensed Practical Nurse [LPN], Mental Health Technicians [MHTs]) is patient safety. Maintaining a safe milieu and maximizing the safety of each patient and staff depends on (1) active, individualized treatment, (2) levels of observation and privileges geared to the patient's level of risk, (3) prompt and skillful response to patient aggression, (4) modification of therapeutic interventions as the nature and/or level of risk changes, and (5) continuing staff education and training.

Level of observation and privileges serve the function of patient safety and should not be used as rewards for compliance with process variables like attendance at groups. When the level of observation is for the risk of harm to self, the most noteworthy harm being suicidality, the hospital needs a process by which increasing the level of observation, that is, more staff oversight can easily be instituted by a physician or RN, but decreasing the level of risk can only occur on a written physician's order after a face-to-face evaluation. In some hospitals, this can only be done by the attending psychiatrist. Telephone orders and verbal orders should never be accepted for lowering the observation level.

In addition to medication, inpatient treatment involves individual sessions and group interventions. Individual psychotherapy is the exception these days, although this modality continues to be used in some public and some private hospitals. There are a few hospitals in which intensive psychotherapy is the mainstay of inpatient treatment. The programming of individual sessions with the social worker to focus on discharge planning is the rule. Individual sessions with nursing staff to practice skills taught in groups should occur at least through the day and evening shifts (and the night shift if appropriate to the patient's needs).

Telegram: @medical_k

www.konkur.in

Group interventions fall under the heading of psychosocial rehabilitation. In general hospitals, these groups occur on the unit. In state hospitals and in some private hospitals, these interventions are delivered off-ward in areas of the hospital, often referred to as the “treatment mall.” There are several advantages to setting up groups or classes in a centralized location, including the following:

1. Patients follow a variant of the “work order day”; patients, like staff, “commute” to where they spend their daytime hours; in the case of patients, they live in one place (the unit) and get their treatment in another location (the mall); lunch is often provided at the mall.
2. Pooling patients and consequently pooling staff means that a large number of different groups can be provided per hour, rather than having the same group occur simultaneously in multiple locations.
3. The issue of patients remaining in bed, watching TV, or participating in other diversions is handled by institutional policy and practice rather than day by day, case by case.
4. The safety of staff and patients is increased because there is more staff available for an emergency.
5. Professional and paraprofessional staff spend more time with patients because patients and staff are at the treatment mall during mall hours.

Newly constructed hospitals (see Table 56.3–1) are designed with accessible treatment mall locations. The use of perimeter security with significant freedom of travel for patients within the building eases access to mall-based treatment and maximizes patients’ autonomy (see Fig. 56.3–5). One controversy surrounding the use of treatment malls at hospitals is whether or not the hospital can require all patients to attend the mall. Does the right to refuse treatment also mean the right to not go where treatment is provided? In one model, patients have a right to refuse treatment, but patients do not have a right to determine where they are at the hospital at any given time. If this were a right, patients could refuse to remain behind any locked door. Patients must go to the treatment mall, but the hospital must provide a place for them on the mall if they refuse to attend the groups they are scheduled to attend. A corollary controversy in this model relates to the issue of whether staff can lay hands on a patient if the patient refuses to go to the mall. Staff can lay hands on a patient if there is an emergency, and leaving a patient on a ward with no staff because of the patient’s refusal to leave the ward would constitute an

Telegram: @medical_k

www.konkur.in

emergency. In another model, where patients cannot be compelled to leave the unit for groups, hospitals have created units with and without an off-unit requirement. There are benefits and drawbacks of each type of unit and absent safety concerns; a patient makes his choice based on his valuation of the different benefits of each type of unit.

Although there are no controlled studies of the operation and effectiveness of treatment malls, data collected at individual hospitals seem to support (1) rapid adjustment of patients to a change to the treatment mall approach; (2) very low use of hands-on procedures to move patients; (3) decreased rates of seclusion and of restraint without accompanying increases in the total daily dose of antipsychotic and/or antimanic medications or of benzodiazepines; and (4) improvement in patients' sleep with fewer doses of hypnotics. Most importantly, patients do seem to learn skills through the use of mall-based groups.

Clinicians doing hospital-based treatment, just like their colleagues doing outpatient treatment, need to be mindful of three contemporary concepts: recovery, evidence-based treatment, and trauma-informed care. Practitioners of all clinical disciplines have struggled to achieve consensus definitions of these percepts. SAMHSA's definitions are as follows:

Recovery: A process of change through which individuals improve their health and wellness, live a self-directed life, and strive to reach their full potential.

Evidence-based: Demonstrating effectiveness in empirical research that meets a standard of scientific rigor as embodied in minimum review requirements, which include the stipulation that an intervention must have demonstrated one or more positive behavioral outcomes ($P \leq .05$) in substance abuse and/or mental health in at least one study using an experimental or quasi-experimental design.

Trauma-informed care: It is a strengths-based service delivery approach that is grounded in an understanding of and responsiveness to the impact of trauma, that emphasizes physical, psychological, and emotional safety for both providers and survivors, and that creates opportunities for survivors to rebuild a sense of control and empowerment.

A well-functioning psychiatric hospital would incorporate these principles into its therapeutic offerings by having expertise in and

Telegram: @medical_k

www.konkur.in

providing, among other offerings: cognitive behavior therapy for psychosis (CBTp) cognitive enhancement and restructuring therapy (CERT); cognitive restructuring for PTSD; cognitive therapy for psychosis (CT-R); dual recovery (mental illness and substance abuse); dialectical behavior therapy; family support and treatment; fire-setting treatment; grief therapy; illness management and recovery (IMR); individualized exercise plan (IExP); leisure skills development; medical care and treatment; mental illness and problematic sexual behavior treatment (MIPSB treatment); motivational interviewing and motivational enhanced therapy; person-centered approach; pharmacotherapy; positive behavioral support plan; readiness for change interventions (individual and group); sensory modulation; vocational rehabilitation; and wellness management recovery action plan (WRAP). Behavioral interventions, generally under the direction of a psychologist with particular expertise in this area, need to be available at all hospitals. This is of paramount importance in hospitals that have units with intermediate- or long-stay patients. The behavioral plan is based on a functional assessment of the target behavior to be modified or eliminated. The plan provides a series of responses aimed at reinforcing some behaviors and extinguishing others. All direct care staff must be trained in the specific interventions to be used for a specific patient. Preferably, the hospital has a way to document such training and to ensure that any staff assigned to work with a patient who has a behavior plan is trained in that plan.

During hospital treatment, a major controversy has been patients' "right to smoke." It is unclear how this is a right. If it were, patients would also have a "right to drink." No one argues the latter, so why the former? Forbidding smoking on the unit has generally occurred at all hospitals. Moving that restriction to a designated area within the hospital was the next step. Patients can often be seen at the perimeters or in the courtyards of the hospital smoking. Many hospitals have progressed to prohibiting smoking anywhere in the building, and some even prohibit smoking on the hospital grounds. Hospitals should neither be in the business of selling cigarettes nor use staff to purchase cigarettes for patients—a practice referred to as "making a cigarette run." Given that there is now a range of aids to stopping smoking—gum, patches, pills, support groups—these should be made available to patients and to staff. Nicotine replacements should be used as a transition to becoming nicotine-free; too often, they become permanent fixtures on the patient's

Telegram: @medical_k

www.konkur.in

pharmacologic plan. It was not that long ago that state hospitals received free tobacco from cigarette companies, purchased cigarette papers, and paid staff, and/or had patient groups whose focus was to roll cigarettes. The rolling machines had been purchased with state funds. Progress in smoking cessation needs to continue, particularly given the increased morbidity and mortality of persons with chronic mental illness. The role of the hospital should be to teach patients and support their efforts to maximize a healthy lifestyle. Wellness programs are being conducted at many hospitals and are well worth supporting.

Discharge Planning

The aphorism "Discharge planning begins at the time of admission" is, of necessity, particularly true today, given all of the pressures surrounding the length of stay. Although the discharge process is primarily the responsibility of the IDT's social workers, it is a mistake to assume it is their task alone. Discharge planning is an interdisciplinary process.

Discharge planning is processed by the social worker interacting with the patient and IDT members until the TRP. At this point, the discharge plan becomes an integral part of the TRP. Whether discharge-related issues are identified as one of the problems on the TRP depends on the patient's specific circumstances. Discharge might be a problem if the patient is homeless, cannot return to the residence from which they were admitted, or is an illegal immigrant with no eligibility for entitlements. An often-missed problem related to effective discharge is recidivism; that is, the patient has multiple admissions, generally with short community tenure between them. Recidivism is often too quickly ascribed to noncompliance with medication without the IDT doing a thorough investigation of the etiology of repeated admissions. Noncompliance may well be a factor in any short time period between admissions, but this may also be accounted for by a number of other factors. Often ignored is the contribution to stabilization made by the structured environment of the hospital. This is often the primary factor in recommending discharge to step down over "home" to allow for transition with continued structure. Often commented on but inadequately addressed is the use of alcohol, marijuana, other street drugs, and other prescribed medication even in a medication-compliant patient. There is also the contributing factor of secondary gain—the hospital may be the locus of the best quality of life the patient has experienced for years or even decades.

Telegram: @medical_k

www.konkur.in

Discharge planning involves the establishment not only of sites of service and appointment times but also of efficacious linkage strategies. The steps that need to be taken to maximize the likelihood that the patient will actually make it to their first appointment with the outpatient psychiatrist are of paramount importance. Linkage also involves providing to the outpatient psychiatrist, outpatient therapist, and other appropriate personnel pertinent information in writing. A copy of the instructions given to the patient should reach the outpatient sites *before* the patient arrives for their first appointment; the discharge summary needs to follow shortly thereafter. So too does the TRP, so that the community can incorporate the work the hospital has done into the community TRP, just as the hospital incorporated the work the community had done into the hospital TRP. Phone contact from inpatient psychiatrist to outpatient psychiatry is advisable for any case seen as needing more than the usual written communications.

SPECIAL POPULATIONS

This section has focused on the role of the hospital in serving the general adult psychiatric population. The hospital serves many other populations, defined either by their demographics or by specific service needs.

Children and Adolescents

Twenty-one percent of U.S. children aged 9 to 17 years have a diagnosable mental or addictive disorder causing at least minimal impairment, and 5% to 9% of children this age have a serious emotional disturbance that causes extreme functional impairment. Significant numbers of children and adolescents in need of treatment do not receive behavioral health services. When children's mental health services are unavailable, unaffordable, or inappropriate, many young people end up in the child protection or juvenile justice systems.

Children and adolescents represent approximately 7% of the total mental health inpatient population. However, children's services receive a disproportionally low fraction of what adults receive for inpatient services, despite the fact, that on average, children's inpatient treatment is about 1.5 times as expensive as adult inpatient treatment.

Although the number of available inpatient psychiatric beds decreased, the admission rates of children and adolescents to psychiatric hospitals

Telegram: @medical_k

www.konkur.in

increased over the last few decades. Between 1986 and 1997, the number of youth admitted to inpatient services increased by 143%, and the rate per 100,000 youths increased by 119%. As the number of inpatient beds and specialized staff to care for children and adolescents with serious emotional disturbance has decreased, the number of families relying on hospital EDs for psychiatric services has increased. ED physicians report seeing a large number of children whose parents have simply run out of options for care.

Inadequate hospital-based and other services have created cohorts of labeled children. “Boarder kids” are children stuck for days, weeks, or even months in pediatric wards because there are no beds in a psychiatric hospital or ward. “Wait-list kids” wait months for case management or outpatient services. “Stuck kids” are in psychiatric hospitals but cannot leave because there is no place for them to go.

There are many factors that complicate the role of the hospital in the care and treatment of children and adolescents. Alcohol and illicit drugs are major problems. Current alcohol use is 36.2% for 17-year olds, 19.9% for 15-year olds, and 6.5% for 13-year olds. Among youth ages 12 to 17 years, about 12% are current illicit drug users. Annual suicide attempts in 15- to 24-year olds have surpassed 1 million in the United States, and suicide is the third-leading cause of death for this age group. Age-specific mortality rates from suicide are 1.6 per 100,000 for 10- to 14-year olds, 9.5 per 100,000 for 15- to 19-year olds, and 13.6 per 100,000 for 20- to 24-year olds. Almost half of the students with mental disorders drop out of grades 9 through 12, and of those dropouts, 73% are arrested within 5 years of leaving school. Children and adolescents with serious emotional disturbance often live in families with multiple risk factors and vulnerabilities, including single-parent households, poverty, and family history of substance abuse, violence, mental disorders, and/or felony convictions.

Although the challenges for families of children and adolescents with emotional and behavioral problems are great, best practices emphasize collaboration with families when coordinating care for the child. Inpatient facilities have placed an increasing emphasis on incorporating the family and other relevant support systems into a child’s treatment plan.

Today, children and adolescents are likely to receive mental health services in what is referred to as “systems of care.” Systems of care provide a spectrum of mental health and other necessary services

Telegram: @medical_k

www.konkur.in

organized into a coordinated network from community-based and least restrictive treatment settings and case management to intensive inpatient psychiatric care. Systems of care rely on “wraparound services.” The values underlying systems of care include a focus on the individual child and family, the provision of services within the most normalized environment that meets the youth’s need, the creation of partnerships with families, the use of a strength-based orientation, the creation of an environment of cultural competence, the provision of unconditional care, and the use of 24-hour institutional care at various points in time. Systems of care do not eliminate the need for inpatient level of care but often shorten lengths of stay.

As the wraparound model appears to have evolved into a best practice in the care of the most difficult children and adolescents, it is important to note that inpatient hospitalization treatment is not a failure of the wraparound model but one of its service components. Thus, the hospital plays a key role in wraparound services.

A challenge that most states face is providing services to children with emotional and behavioral disturbances when they age out of the child system. The eligibility requirements for services in a state’s adult system are many times narrower than the eligibility in the child system, so some transition-age youth who have been receiving services for years are screened out, leaving them without care and treatment. A vulnerable time for a young adult is exacerbated by the states’ need to restrict its eligibility pool for publicly funded mental health services.

Veterans

The veterans’ hospital system was established after World War I when veterans were entitled to health care benefits and compensation. States were unable to handle the needs of this population, given that there were hundreds of thousands of U.S. soldiers “wounded not mortally” and uncounted numbers who suffered from neuropsychiatric conditions.

On his last day in office in 1921, President Woodrow Wilson signed into law a bill supporting $18.6 million for the establishment of hospitals for veterans. The years 1921 to 1923 saw the provision of more than 6,000 beds in new veteran’s hospitals across the United States. From 1923 to 1945, there was a considerable expansion of hospital beds. Following World War II, the VA was entirely reorganized. In the decades following World War II, VA hospitals accounted for only a small percentage of the

Telegram: @medical_k

www.konkur.in

hospitalized population. Trends in bed use shifted, however, such that between 1955 and 1975, the number of VA inpatient episodes increased by 143%, whereas state and county mental hospitals decreased by 37%.

In the mid-1990s, the VA shifted its traditional focus on inpatient care and dramatically expanded its outpatient services. Between 1995 and 2001, the number of occupied annual inpatient psychiatry beds fell by 58% in VA hospitals, the length of stay decreased by 52%, and the number of veterans treated in the VA outpatient system increased by 27%. This shift, and the reorganization of the Veterans Health Administration (VHA) into 22 smaller, semiautonomous networks, may be contributing to the VA's apparent inability to meet the needs of veterans from combat in Afghanistan and Iraq. And that need is substantial. A nationally representative sample drawn from the National Health and Resilience in Veterans Study showed that the current and lifetime prevalence of PTSD in veterans was 4.8% and 8%, respectively. PTSD came from combat and noncombat situations and was associated with elevated risks of severe psychiatric disorders and suicide.

Efforts were initiated in 2006 to substantially improve the capacity of VA hospitals to meet the increasing psychiatric need of veterans. The VHA struggled to provide the necessary service. A 2010 report estimated that 18 veterans a day die by suicide and 950 suicide attempts occur each month among veterans receiving services through the VAH. Between 2010 and 1014, VA hospitals were the subject of scandals and problems, with systemic problems including turning away veterans who needed services and who then suicide, maintain secret waiting lists to create the appearance that delay in service was much shorter than it was, putting out false performance reports, covering up suicide attempts and running facilities in which illicit drug dealing was routine practice. As one commentator said, "the VAH is a bright, shining example of misguided priorities and terrible mismanagement."

Veterans seek and/or receive treatment out of VHA settings for a number of reasons: The veteran is not service-connected for a psychiatric disability, the veteran prefers treatment out of the VHA, the veteran is a committed pursuant to a forensic status, or in some jurisdictions, the veteran refuses voluntary admission and requires civil commitment. Thus, continuity of care can be particularly problematic as the veteran moves in and out of the VA, public, and private systems of care.

Telegram: @medical_k

www.konkur.in

The challenges facing the VAH are significant. In 2014, there were 24 million veterans in the United States, about one-third of whom were enrolled in VA care. There are 21,000 mental health professionals to meet this need, but only 3,000 are psychiatrists. The expectation is that the Veterans Access, Choice, and Accountability Act of 2014 will improve the ratio of VA psychiatrists, non-VA psychiatrists, and other mental health clinicians available to treat veterans with psychiatric disorders. The VA MISSION Act authorizes or expands several programs with the intention of recruiting and retaining health care providers in the Veteran's Health Administration. Among other things, the Act increases the maximum amount of student loan debt that may be reduced under VA's Education Debt Reduction Program (EDRP); authorizes designated scholarships for physicians and dentists under the VA Health Professional Scholarship Program (HPSP); establishes the VA specialty education loan repayment program to incentivize VHA employees to pursue education and training in medical specialties for which VA determines there is a shortage; establishes a pilot Veterans Healing Veterans Medical Access and Scholarship Program, and extends eligibility for VA's EDRP to clinical staff working at Vet Centers. The Veterans Access, Choice, and Accountability Act of 2014 (VACAA) required an increase in the number of GME positions by up to 1,500 over a 10-year period, beginning July 1, 2015, through 2024, with an emphasis on primary care, mental health, and other specialties the VA Secretary deems appropriate. The VACAA also required that the expansion focus on creating new programs at VA facilities where there had not previously been GME training and that the new positions be awarded for training in rural or otherwise underserved areas. As of September 2017, the VA had allocated about one-third of these new positions; it has not completed the expansion. Instead, the VA's objective is to complete the expansion by 2025.

Individuals active in the military receive their psychiatric inpatient treatment in Department of Defense hospitals. Of major concern for this population is suicide. The U.S. Army suicide rate exceeds the civilian suicide rate with substantially elevated suicide rates following psychiatric hospitalization—an eightfold increase for 3 months following a psychiatric hospital discharge and a fivefold increase for 12 months after psychiatric hospitalization. The Patient-Centered Community Care (PCCC) program contracts were awarded in September 2013 to provide inpatient and outpatient specialty care and mental health care for eligible veterans when

Telegram: @medical_k

www.konkur.in

the local VAMC cannot readily provide the services, such as when there is a lack of available specialists, there are long wait times, or there is an extraordinary distance from a veteran's home.

Substance Abuse Comorbidities

Persons whose alcohol and/or substance use require hospital-based treatment fall into two categories: Those with so-called "straight substance abuse," meaning that there is no other mental illness that is the focus of treatment, and persons who are dually diagnosed with a mental illness and a substance use disorder both of which require active treatment.

Treatment for substance use in either population requires detoxification when such is necessary and then treatment initiating prevention of relapse and recovery. Relapse and recovery are lifelong enterprises that may or may not involve inpatient treatment. With the exception of detoxification of persons at high medical risk, all the services for persons with substance abuse or individuals dually diagnosed can be found at a hospital and nonhospital loci of care.

Perhaps the major shift in the treatment of persons with dual disorders that occurred in the latter part of the 20th century was the movement from consecutive treatment to concurrent treatment. For decades, there was the belief that one could not address other psychiatric disorders until one had first addressed alcohol and/or substance abuse or dependence. Currently, efficacious treatment is considered to be treatment that addresses both at the same time.

Because the rate of alcohol and substance abuse is quite high in persons with other *Diagnostic and Statistical Manual of Mental Disorders*, fifth edition (DSM-5) disorders, hospitals need to have expertise in substance abuse assessments and treatment at all levels of service. Many a diagnosis will be missed if the attending psychiatrist or the C-L psychiatrist is not thinking about the potential roles that alcohol and illicit drugs may be playing in the patient's presentation. The legalization of marijuana or medical marijuana in some states is presenting new dilemmas for psychiatric hospitals and C-L psychiatrists. It is too soon to tell how this will be dealt with in different states, and within one state, in psychiatric inpatients settings in different types of hospitals.

Geriatrics

Telegram: @medical_k

www.konkur.in

Patients older than the age of 65 years and those deemed “functionally geriatric” are treated in units with mixed-aged populations in some hospitals and on psychogeriatric units in others. The involuntary admission of older adult individuals varies greatly from state to state, in that some state statutes prohibit the involuntary admission of persons with any form of “organic brain syndrome” as the basis for the commitment, whereas others do not.

Older adult patients have special needs that the hospital must attend to (1) greater comorbidity with medical disorders; (2) increased likelihood of delirium; (3) possibility of their having another disorder that is confused with dementia, especially major depressive disorder; (4) greater need that all other medications they are taking be considered when the assessment is done and when psychopharmacologic recommendations are made; (5) higher suspicion for impaired capacity to consent to treatment; and (6) more likely to need additional social work care and services to assist for example in Adult Protective Services (APS) reports, identifying and contacting alternative decision markers, addressing end of life care concerns.

Of particular concern is the use of antipsychotic medication in older adult patients. In 2005, the FDA warned that second-generation antipsychotic medication was associated with an increased risk of death in older patients with Alzheimer’s disease and other age-related dementias. In 2008, the warning was expanded to include first-generation antipsychotics. Subsequently, a Harvard Medical School study of older adults, new users of antipsychotic medication showed that haloperidol had twice the mortality rate of the atypical antipsychotics, and among the atypicals, quetiapine had the lowest mortality rate. Another class of medications of concern is benzodiazepines, ubiquitous in their use in hospital settings to quiet agitated patients, including older adults. A case-controlled study using Quebec, Canada health insurance data showed chronic use of benzodiazepines by older adult patients was associated with about a 50% increase in Alzheimer disease 5 to 10 years after a period of 90 or more days of use, with benzodiazepines with half-lives of greater than 20 hours carrying the greatest risk. Thus, caution should be used in the inpatient management of older adult patients by using benzodiazepines for longer than brief—up to 90 days—treatment.

Staff in any of the hospital services should consider the need for, and implement if necessary, a complete organic medical workup, formal

Telegram: @medical_k

www.konkur.in

cognitive assessments, and referral for follow-up services that are age-sensitive.

Developmental Disabilities Comorbidities

Most states have deinstitutionalized persons with developmental disabilities/delays at an even greater pace than their population with chronic mental illnesses. That means that former residents of developmental disability facilities who would not have been seen for hospital treatment now are.

Persons who present for services at hospitals with anywhere from mild to profound developmental disabilities may be coming from their home where they live with parents, from community residential programs where they live with staff, or, in the case of mild mental retardation, from an independent living arrangement. In each instance, the person needs individualized services that are informed by their capacities. Especially important is the use of concepts and language the individual can comprehend.

Serving persons with developmental disabilities in the hospital has evolved in many different ways. In most hospitals, these individuals receive services in the same areas of the hospital as all others. There are certain disadvantages to this approach in that the essential skills to meet the needs of the population may be lacking. There are a few general hospitals that have specialty units to serve persons with developmental disabilities and even more state hospitals that do.

When the person with developmental disabilities presents for services at the hospital, it is most often due to unmanageable behavior. That is not to say that individuals with developmental disabilities do not become psychotic, depressed, or anxious; they surely do, and these conditions need psychiatric attention. However, a majority of persons dually diagnosed with a mental illness and developmental delays present because they can no longer be dealt with in the environment in which they live. Commonly the individual receives such diagnoses as impulse control disorder not otherwise specified, intermittent explosive disorder, or, if adolescents or younger children, conduct disorder or oppositional defiant disorder.

Persons with developmental disabilities should leave the inpatient setting with a functional analysis of the problematic behavior that permits the outpatient setting to follow through with treatment that will facilitate

Telegram: @medical_k

www.konkur.in

habilitation. Often this entails the use of behavioral interventions. All hospital treatment of persons with developmental disabilities entails close collaboration with the team of persons providing all outpatient and residential services. Collaborative treatment is essential in the hospital's achieving successful outcomes with this population.

Medical Comorbidities

Psychiatric disorders complicated by or complicating medical disorders are a common occurrence. Psychiatric services are often required when there is a diagnostic question related to mentation or mood; when a patient is too "out of control" or their behavior is so "inappropriate" that management of the patient is not going well on the medical or surgical services; when the medical or surgical practitioner cannot communicate with the patient or cannot obtain informed consent; or when there is an ethical question about the course of treatment.

There is perhaps no better example of the psychiatric hospital's role in treating persons with medical illness than HIV infection. There is a bidirectional relationship between severe mental illness and HIV infection; persons with psychiatric disorders are at higher risk of acquiring HIV, and persons who are HIV positive have increased rates of psychiatric illness. The interactions between disorders and treatments are myriad. Psychiatric disorders may impair judgment and heighten the risk of contracting HIV (e.g., mania in bipolar disorder) or lead more directly to increased risk (e.g., intravenous drug use). HIV can induce, both psychologically and by a direct effect on the brain, anxiety, depression, psychosis, and dementia. Antiretroviral medications can induce psychosis. Drug–drug interactions—drugs prescribed for HIV status, psychiatric status, and medical disorders due to HIV status—make treating the comorbid psychiatric disorders quite complex. Being HIV positive per se, the symptomatology of HIV, the psychiatric disorders that predated HIV-positive status, and the psychiatric disorders resultant from being HIV positive may all diminish compliance with both retrovirals and psychotropics.

The hospital plays a unique role in meeting the clinical needs of persons who are HIV positive. Although the general hospital is the mainstay of treatment for this population, the state hospital is not infrequently called on to provide care and treatment to symptomatic and nonsymptomatic HIV-positive individuals.

Telegram: @medical_k

www.konkur.in

Although HIV infection has been used as an example, a comparable presentation could be made for scores of medical disorders. Some, such as systemic lupus erythematosus, temporal lobe epilepsy, and space-occupying brain lesions, are dramatic examples. On a more frequent basis, hospital-based psychiatric and medical services draw together to treat such conditions as cancer, renal failure, and trauma.

Psychiatry has known for over 150 years that individuals with SMI die younger than persons without these disorders. And the reason for this is still unknown. It is known that medical comorbidities can be significantly exacerbated by psychiatric medications. This is no better illustrated than metabolic syndrome in persons taking some of the second-generation antipsychotic medications. It behooves the inpatient psychiatrist to work closely with his medical colleagues in the hospital and other staff like dieticians and occupational therapists to create and monitor wellness programs for his patients.

A service that has become standard in many state hospitals is hospice care. These services are provided to the state hospital patient who has spent some time in the hospital and without the patient needing to be transferred to another facility or even to change units within the hospital. The advantages to the patient are many, but the fundamental advantage is the patient's ability to remain in a familiar environment with staff he is comfortable with. It is important to have the patient's informed consent or the guardian's if a guardian of the person is in place, for all services that will not be provided and those that will. Hospice care in the hospital works closely with families and significant others throughout the patient's stay to process bereavement and loss.

Deaf Individuals

In treatment as orally based as is psychiatric treatment, the clinical approach to persons who are deaf presents a unique set of challenges. Although in many states, deaf individuals who need psychiatric treatment secure that treatment within the hospital alongside all others with the addition of translation services, some states have a statewide deaf unit at one of its hospitals. Here, persons who are deaf can interact with staff without the imposition of a translator and can be in an environment that is sensitive to the deaf culture. There are very few private hospitals that offer this service.

Telegram: @medical_k

www.konkur.in

The range of the hospital's roles in treating deaf persons is no different than for hearing persons. To fulfill that role, hospital staff needs to be aware of and sensitive to the deaf culture. For this population, the state hospital-based deaf unit may be the least restrictive, most integrated setting when inpatient treatment is required. In states with deaf units that also require civil admissions only come from other hospitals, this restriction is waived for the deaf population who can be direct admits from multiple loci of care, including general hospital EDs.

Forensic Patients

Persons admitted to the hospital pursuant to the commitment of a crime are the states' responsibility and one that the state generally fulfills directly at state hospitals. There are a few exceptions when the state contracts out for these services.

Forensic patients are in the hospital basically for one of three reasons: (1) pretrial, for a determination of competency to stand trial and/or of criminal responsibility for the crime; (2) after a finding of being incompetent to stand trial, guilty but mentally ill, or not guilty by reason of insanity; or (3) jail or prison could not manage the inmate due to his behaviors as a result of psychopathology. Restoration of competency to stand trial is a unique forensic task, and the hospital needs to have specialty functions to accomplish this. Much of the rest of the clinical treatment of the forensic population is the same as that of the nonforensic population. Security on forensic units is generally much tighter than in other places at the hospital.

Often the role that the hospital is required to fulfill for many forensic patients is one that it does not play very often for other patients—housing forensic patients for years to decades beyond the time the patient needs hospital-level care. The degree to which this occurs is heavily dependent on the state commitment statutes and procedural handling of its forensic patients.

Although there is a clear dichotomy between forensic and nonforensic patients based on the state statute under which the patient was admitted, the clinical variation and treatment need to show no such distinction. Whether a patient is civil or forensic, especially for minor crimes, has more to do with the circumstances of the patient's initial encounter with the police than it does with their clinical presentation. The boundary is

Telegram: @medical_k

www.konkur.in

also blurred these days because of states admitting more persons at the end of a criminal sentence, especially those convicted of sexual offenses.

The hospital has multiple roles with the forensic patient: (1) to meet the person's needs as a psychiatric patient, (2) to meet the state's needs to proceed with due process in trials, and (3) to maintain the public's safety in the face of those who break or are charged with breaking state or federal law. Hospitals are considerably more comfortable with the first role than with the other two.

With forensic patients, the judicial or quasi-judicial systems control the admittance and discharge of patients. In many states, this contributes to both overcrowding at hospitals and to an ever-increasing percentage of forensic patients in the hospital's census. It is an irony of current times that jails and prisons feel overwhelmed by inmates sheriffs believe should be psychiatric inpatients, and psychiatric hospitals feel overwhelmed by inpatients psychiatrists assess to need jails and prisons.

OTHER HOSPITAL ROLES

This section has focused on the inpatient functions of the hospital, which comprise the service that is unique to it. The hospital fills a number of other roles, many of which are also performed in some fashion by entities that are not hospitals.

Emergency Services

Psychiatric treatment is provided on an emergency basis in hospital EDs (see Fig. 56.3–1). The arrangements under which this is done vary greatly. In community hospitals, the person presenting with a psychiatric problem is generally treated in the same fashion as all individuals—the same waiting area, the same examining rooms, sometimes the same physicians. In larger hospitals, all of these functions are often segregated into a designated area of the ED where patients are seen by nonphysician evaluators who consult with psychiatrists who may or may not see the patient. Like many other hospital functions, crisis evaluation services have moved out of the hospital and to freestanding crisis services in some jurisdictions. Not uncommon is a hybrid model in which the hospital ED plays host to an outside crisis service. Here, the hospital performs medical screening evaluations.

Telegram: @medical_k

www.konkur.in

The ED functions may include psychiatric holding beds, that is, the ability to keep a person in the ED for up to 23 hours, thus avoiding an admission. The ED may include crisis beds, a service allowing a short number of days that again avoid admission to the psychiatric unit. Crisis beds are another service the hospital shares with nonhospital settings such as CMHCs, which offer freestanding crisis beds.

Psychiatric patients "stuck" in ED's awaiting transfer to an inpatient bed have become a nexus for consternation over inadequate inpatient beds. These patients can wait hours, days, weeks, or in some cases over a month, during which time little is done for them other than room and board in the ED. In August 2014, the Supreme Court of Washington State found (*IN RE the Detention of DW et al.*) it unlawful, under Washington's involuntary treatment act, to board patients in EDs just because the appropriate evaluation and treatment facilities are overcrowded.

Only about half the states have processes in place to systematically identify open beds for psychiatric patients who need admission. Even those states that can effectively search for bed availability are stuck with the inadequate number of psychiatric beds nationwide. A 2012 study by the Treatment Advocacy Center, "No Room at the Inn," demonstrated that not one state had sufficient numbers of public hospital psychiatric beds.

Step Down/Admission Diversions Services

Hospitals offer a range of services that function between inpatient and outpatient levels of care. Such services include day hospital, partial hospital, and night hospital. In treatment arrangements that are during the day, the individual attends a full day of active psychiatric treatment but lives outside of the hospital, for example, in their home, with family, or in a community residential program. In the night hospital program, the person leaves the hospital for school or work during the day but spends overnights at the hospital. All of these programs are also used as attempts at admission diversion, that is, to avoid inpatient hospitalization for this episode of illness. Step-down programs and admission diversion programs are also offered by nonhospital entities, with the latter also offering respite beds. These have a longer length of stay than crisis beds and are not generally provided by hospitals.

Partial hospital programs, once enthusiastically endorsed by insurers as less expensive alternatives to inpatient treatment for their use as both alternatives to admission and step-downs to decrease the length of stay,

Telegram: @medical_k

www.konkur.in

have lost favor. There is a dwindling supply of such programs. Just between 2000 and 2001, the number of facility members of the National Association of Psychiatric Health Systems (NAPHS) offering partial programs decreased from 83% to 67%. Between 2003 and 2013, the number of hospitals offering partial programs decreased by 20% (from 508 to 410). There is expected to be further loss of partial programs if CMS decreases their reimbursement rate, as it is proposing to do.

Outpatient

Outpatient services are offered in more settings than any other service. Besides the hospital, outpatient services are found in CMHCs; group settings, either integrated with primary medical services or at their own sites; private practices; family services agencies; and hosted in locations such as shelters, specialty clinics, mental health residential programs, and mobile units. Payment for these services is most often by third-party insurers—private or government—with a copay by the patient. In larger metropolitan areas particularly, some outpatient providers have established practices that take no insurance.

The major challenge facing outpatient psychiatry at hospital locations is the high cost of delivering the treatment within hospital settings and the poor reimbursement rates. It has reached the point where expanding business in the outpatient department (OPD) is the last objective of the hospital because each new patient adds to the deficit.

On a more practical note, hospitals are seen as unfriendly places to the individual seeking outpatient psychiatric services. Parking is often difficult, far from the OPD, and expensive. Negotiating the corridors of the hospital is a challenge that many would prefer to avoid. In addition, the patient may have to go through a registration process that simply adds another layer of annoyance.

The prognosis for hospital-based outpatient services is not good. Often the victim of cherry-picking by others (the most difficult patients are directed to the hospital OPD), the hospital psychiatric OPD is on the hit list of many hospital chief executive officers. One remedy may be hospital-based integrated clinics where outpatient psychiatry and medicine are collocated. Such attempts have been around for 40 years, but the momentum for such integration is accelerating.

Consultation-Liaison

Telegram: @medical_k

www.konkur.in

Although many hospital executives would gladly replace the psychiatric inpatient service with more profitable medical-surgical beds and make much better use of the space devoted to the psychiatry OPD (which is often banished from the main hospital buildings anyway), the C-L function is usually highly valued. In part, that is because the C-L service directly affects the hospitals' medical and surgical services by evaluating patient's capacity to consent, assessing cases of delirium and psychosis, and assisting with difficult dispositions. The C-L service can be invaluable in making differential diagnoses that will fundamentally alter treatment and disposition. Some have argued that it is because a hospital could not effectively function without C-L psychiatry that much of the rest of hospital-based psychiatry is tolerated. This may be a somewhat cynical overstatement, but it certainly has some elements of truth. A well-functioning C-L service is a fountain of goodwill for the psychiatry department.

Community Education and Patient/Family Support

One role of the hospital that is largely one of goodwill is the hospital's role as host to a remarkable array of self-help and support groups. Those that fall under the penumbra of mental health and substance abuse activities are frequent in hospitals; such groups are Alcoholics Anonymous, Narcotics Anonymous, and the National Alliance on Mental Illness. Less directly related to mental illness but using principles of support are groups centered on all manner of chronic conditions and issues, such as breast cancer, colostomy, and scleroderma. There are also groups for individuals in specific life circumstances, such as parents without partners and parents who lost a child to cancer.

Hospitals also play a community education role. Members of the psychiatry staff may provide substantive lectures geared to the lay public. These are different yet complement the hospital's psychiatry grand rounds, which themselves are usually open to the public. Another form of education is informing the public about the services the hospital has to offer.

FUTURE DIRECTIONS

The challenges that face hospitals in the second decade of the 21st century are not new. Prior to 1950, virtually every problem and many of

Telegram: @medical_k

www.konkur.in

the solutions that define contemporary hospital psychiatry were noted in the professional literature. One need only read such sources as the *American Journal of Insanity*, *Alienist and Neurologist*, or state hospital annual reports to find them all.

Homelessness, the overpopulation of jails and prisons with persons with mental illness, the eschewal of persons with mental illness from any locale because that jurisdiction does not want financial responsibility for the person, an inadequate focus on treatment and overreliance on management, and a propensity to not spend tax money on persons with mental illness are all conditions Dorothea Dix found in the 1840s when she began her lifelong work of reform. Samuel Woodward, APA's first president and the first superintendent of what is now the Worcester Recovery Center and Hospital (see Figs. 56.3–4 and 56.3–5), would have recognized them all.

The loss of the person in meeting the acute needs of the patient, the reliance on modern technologies for diagnoses that have diminished one-to-one time with patients, and the general sense of the dehumanization of psychiatry and medicine, in general, were noted by William Allison White in 1925. White remarked in his APA presidential address that "the introduction of these highly technical methods has been accomplished by a corresponding lack in development, at least, if not actual loss, of any adequate dealing with the patient as an individual or as a human personality."

Even hospitals bending to the dictates of payers to minimize costs is not new. More than 125 years ago, Kirkbride lamented that "it will be a sad day for these institutions, and still sadder for the patients in them, when the rivalry of hospitals and their offices shall be, rather to discover for how little inmates can be kept, than to secure what is best, and most thoroughly promotes the great objects for which they were established."

State hospitals are disappearing by design. Whether that is the result of thoughtful or ill-conceived planning is a matter of debate. General hospital psychiatry programs, however, are disappearing through a thoughtless process of survival of the fittest.

Reimbursement and operating margins for psychiatric services lag behind those of other hospital-based medical services. The diminishing financial returns from psychiatry have led hospital management consultants to recommend converting psychiatric beds to higher-margin medical and surgical beds. Even to remain fiscally viable now, psychiatric

Telegram: @medical_k

www.konkur.in

hospital inpatient revenues need to cross-subsidize emergency, consultation, and outpatient services.

Today, psychiatrists generally fail to acknowledge those times when the psychiatric hospital is a forerunner or role model for the rest of psychiatry, if not the rest of medicine. One of the foci of contemporary medicine is the integration of medicine and psychiatry or medical and mental health services. As practitioners in psychiatry and in medicine focus on methodologies to integrate care and treatment, they need look no further than the public psychiatric hospital, which has been an integrated care organization for over 100 years and still is a fine example of integrated care and treatment. Outpatient integration, it seems, is mimicking business as usual at the state hospital but without its walls.

Attributes of a state hospital that contribute to its high degree of integration include:

- Psychiatric and medical services collocated
- An integrated psychiatric and medical treatment plan
- A single shared medical record, now an electronic medical record in many institutions
- Ease of communication among a patient's physicians and between those physicians and other disciplines
- Case or care management integrated into treatment
- Professional and paraprofessional staff assisting patients to follow through with psychiatric and medical recommendations in an integrated housing and care model
- On-site wellness programs, for example, dietary, exercise, organized leisure
- Other health promotion activities, for example, weight loss, smoking cessation, treatment of substance abuse
- Transportation to any off-site medical appointments
- Workforce development, for example, student placements, pre- and postdoctoral internships, residency rotations
- Paid time off for staff education
- On-site dental, podiatry, optometry, radiology, phlebotomy, and neuropsychiatry services
- Peer supports
- Referrals to community and social supports
- Services for all independent of the ability to pay

Telegram: @medical_k

www.konkur.in

- Funding supports not only direct service but time for collaboration
- Unitary billing system
- Transition services for relocation provided and funded
- Interfaces with vocational services
- Provision of in vivo training, for example, bus riding, banking, using the library
- On-site hospice care with direct care staff the patient is already familiar with.

The state psychiatric hospital, as an integrated care system, should have outcome measures that reflect these attributes. The current, common outcome measures fail to take this into account and currently include the number of assaults patient on patient and patient on staff; the number of serious assaults; the number of episodes and time in any form of seclusion or restraint (manual, mechanical, chemical); two or more antipsychotic medications at discharge; five or more psychiatric medications prescribed; time out of the hospital on unsupervised passes; and timeliness of all manner of documentation. Many of these measures are open to interpretation, especially what a facility chooses to label as an episode of restraint. What about improvements in health and wellness as outcome measures?

Virtually no knowledgeable commentator claims that the system of care and treatment for mental illnesses can be sustained without the roles played by psychiatric hospitals. At the same time, too few informed people are working on methods to interdigitate the hospital's roles into the fabric of an integrated system of care, one that looks less like Figure 56.3–1 and more like one that achieves effective outcomes, through a person-centered approach, with fiscal management that does not compromise the very care and treatment psychiatrists are attempting to deliver.

56.4 Mental Health Services Research

Lisa B. Dixon, M.D., M.P.H., and Milton Wainberg, M.D.

The imperative for mental health services research arises from some basic and alarming facts. Over half of the persons with mental disorders receive no mental health treatment. For those who do, the vast majority—approximately 75%—do not receive treatment that can be judged of good quality by evidence-based standards. Those outside of the health services research field, such as clinicians and other stakeholders, may not see how mental health services research can improve the substandard quality of mental health care. In fact, they may not even understand what health services research is. The Association for Health Services Research broadly defines it as:

> Implementation Science is the multidisciplinary field of scientific investigation that studies how social factors, financing systems, organizational structures and processes, health technologies, and personal behaviors affect access to health care, the quality and cost of health care, and ultimately our health and well-being. Its research domains are individuals, families, organizations, institutions, communities, and populations.

This chapter reviews the specific scope of mental health services research and illustrates through several case studies how such research addresses critical questions that arise in the routine provision of services, laying the groundwork for improving the quality of mental health care.

Telegram: @medical_k

www.konkur.in

Notably, implementation science or the study of strategies and approaches to promote the use of evidence-based practices has become a key element of mental health service research.

THE SCOPE OF MENTAL HEALTH SERVICES RESEARCH

Clinicians seek to address identified clinical problems, disorders, and diseases. Clinicians turn to biomedical research to answer two basic questions: (1) What is known about the nature of this problem? (2) What can be done to remedy it or alleviate the suffering associated with it? Research answers to the first question derive from *basic sciences research*, whether biologic (e.g., What neural pathways are affected in bipolar disorder?), behavioral (e.g., How do organisms respond to different types of reinforcement schedules?), psychological (e.g., How do negative automatic thoughts affect mood?), or sociologic (e.g., What are the pathways to homelessness?). Research answers to the second basic question arise from *clinical research* involving well-controlled treatment trials designed to determine efficacy and safety, as well as from the more or less systematic trial and error of clinical experience. Broadly, the basic and clinical sciences deal with the knowledge needed prior to the initiation of routine care. In other words: What is the health problem, and what treatments might relieve this problem? *Health services research* questions, however, arise once clinical services get underway. Clinicians have extensive exposure to the basic and clinical sciences during their training but may have little or no exposure to, and hence little understanding of or appreciation for, the value of health services research and implementation science.

What kinds of questions do mental health services researchers ask? These questions can be divided into two general categories—*clinical services research* and *service systems research*. Like clinical research, *clinical services research* focuses on “front-line” clinical issues and uses individual service recipients (patients, families) as the participants and units of study. Examples of questions asked by *mental health clinical services research* include the following: How effective are antidepressant agents in producing illness remission among typical patients with major depression seen in routine office practices? What considerations influence individuals to seek treatment and to agree to complete a course of

Telegram: @medical_k

www.konkur.in

prescribed treatment? What range of treatments for persons with schizophrenia are “evidence-based?” Do persons with substance abuse and mental illness have better outcomes when they receive care from integrated addiction mental health teams or programs with parallel services? What are the effects of a routine depression screening measure in primary care on detecting and treating major depression in such settings?

Mental health services system research examines questions at the service system level and typically uses aggregated service components (providers, treatment agencies, state mental health systems, etc.) as the units of study. Examples of questions asked by service systems researchers include the following: How many persons with severe mental illness who are being treated in a public mental health system have access to routine primary care? Does this differ between two states with different Medicaid policies? What are the various sites in a city where homeless persons with severe mental illnesses receive services and are these coordinated? What are the effects of a decision by Medicaid to cap the total number of prescribed medications that recipients can receive? Do restricted formularies for antipsychotic medications reduce overall costs? Do they affect quality? Do local mental health authorities improve coordination, continuity, and quality of care for high-need patients?

Implementation science research typically integrates multiple levels to ask how to best implement evidence-based practice.

Given this broad scope of mental health services research, it is also helpful to note what it does not include (Fig. 56.4–1). The distinction has already been mentioned between basic and clinical research on one hand and mental health services research on the other. The interface between clinical research and clinical services research begins at the transition between treatment efficacy and treatment effectiveness studies. *Efficacy studies* examine the outcomes of treatments within narrowly defined samples of patients who are carefully selected to control for variables that might interfere with determining a treatment effect (e.g., the exclusion of patients with comorbid substance abuse or medical disorders). Efficacy study designs attempt to maximize internal validity. *Effectiveness studies* examine treatment outcomes among more inclusive, diverse, and “typical” clinical populations. External validity assumes a more important role. Generally, effectiveness studies only occur after treatment efficacy has been established. Mental health services research, while somewhat

Telegram: @medical_k

www.konkur.in

distanced from the efficacy studies with which many clinicians are familiar, is still *research*, using standardized scientific procedures to answer specific research questions to generate new knowledge that is generalizable beyond the system being evaluated. It should be distinguished methodologically from routine activities undertaken by service systems and service agencies to monitor policy implementation, program or system administration, or quality assurance.

FIGURE 56.4–1. The relationship between basic and clinical research and health services research.

Figure 56.4–1 illustrates the distinction between basic and clinical research and health services research, the flow between these larger research domains, and depicts various activities conducted within health services research. For example, one way in which clinical practice is

Telegram: @medical_k

www.konkur.in

affected by services research occurs as the results of clinical efficacy trials and effectiveness trials are applied to routine practice—a form of "translational research." Given that a primary goal of basic and clinical research is to inform clinical practice when a body of scientific knowledge has accumulated, it should be adopted into clinical practice. However, this translation does not happen as it should; the gaps between existing scientific knowledge about treatment efficacy and effectiveness on one hand and routine clinical practice on the other have been referred to collectively as the "quality chasm" in medical care encompassing both access and quality.

A major question for mental health services research, then, is how to promote the adoption of scientifically validated treatments (evidence-based practices) and, by doing so, bridge the "quality chasm." One response has been the development of evidence-based practice guidelines, variously referred to as evidence-based practices, evidence-based treatment recommendations, or "best practices." The identification of evidence-based best practices is critical to examining current practice patterns, evaluating their quality, identifying areas in need of improvement, and ultimately identifying areas in which current treatments fall short. The methodology for developing such evidence-based practice guidelines emphasizes the results of efficacy and effectiveness research, augmented by expert opinion when research evidence is underdeveloped in essential areas.

Once a set of research-based best practices has been identified, health services researchers can ask a variety of questions about how current practices compare to best practices, including variations in practices across treatment settings, practitioners, and patient subtypes, as well as the relationship to such factors as insurance coverage, health policies and regulations, and cultural diversity. Such research can also examine patterns in outcomes of care across different kinds of services and relate these to patterns in the implementation of evidence-based practices. Such studies are essentially descriptive, but they allow comparisons of actual practices to standards of care.

Identifying gaps between actual and best practices can lead to developing health services interventions to improve care. Such interventions fall into one of two general categories. *Supply-side* interventions focus on individual providers or service programs. These interventions seek to change the care offered in some way. Some

Telegram: @medical_k

www.konkur.in

examples of supply-side interventions include provider education and training programs, systematic feedback to providers regarding their current practices, consultations to agencies about the implementation of best practices, financial incentives to alter practices, and so on. *Demand-side* interventions focus on the demand for services and are directed at changing patient behavior. Examples of such interventions include educating patients about best practices, training patients in how to advocate for themselves in health settings, and providing service vouchers to patients to enable them to select services that they identify as most helpful.

Both supply- and demand-side interventions can occur at distinct levels involving individual providers and patients, local service agencies, local or regional service systems, and local, regional, or national policies. *Shared decision-making* is a strategy that involves both supply-side and demand-side approaches at the level of the individual patient–provider interaction. *Policy-level interventions* occur at the level of a system of care with the intention of changing patterns of service delivery—for example, changing the services covered by insurance, creating local mental health authorities to improve the coordination and outcomes of treatment in a given locale, mandating the integration of mental health and substance abuse services, or offering Medicaid care through a coordinated and managed "health home."

Such interventions, however, are not in themselves health services research. Rather, health services research evaluates the effects of such interventions on a range of outcomes, including patient outcomes, changes in patterns of care, and costs. In health services research, the interventions must be clearly defined, the fidelity of their implementation closely monitored, and the outcomes measured in a standardized form. Research designs to minimize threats to internal and external validity—for example, randomized clinical trials—are critical, as in clinical research. The research questions, although based on specific interventions, focus on knowledge that can be generalized to other settings. As in other areas of research, findings from any phase of health services research optimally feedback to raise new research questions.

Recent work has focused on methodologies for implementation research, a burgeoning domain of health services research that attempts to understand how effective interventions can be implemented. Studies of implementation problems in carrying out interventions at the level of

Telegram: @medical_k

www.konkur.in

systems or individual clinical care depend upon various conceptual frameworks but generally acknowledge the need to study factors including (1) the structural, political, and cultural context as well as internal organization of the settings in which the intervention will take place, (2) characteristics of the individuals involved, (3) the process of implementation of the intervention, and (4) the nature of the intervention itself. Such research takes a pragmatic approach, seeking to understand how real-world conditions affect the implementation of the evidence-based practices for which clinical and other research has established evidence of efficacy and effectiveness.

The following "case reports" concretely illustrate the application of mental health services research to critical questions that arise in the routine provision of services.

Case 1: Treatment of Depression in Primary Care Settings

Depression is one of the most common mental disorders and accounts for a staggering amount of disability worldwide. Over the last several years, there have been substantial improvements in methods for diagnosing depression, and a broad range of efficacious treatments for depression exist, including antidepressant medications and evidence-based forms of psychotherapy. A number of evidence-based practice guidelines have been developed, so the opportunities to effectively diagnose and treat depression are substantial.

Given the state of diagnostic and treatment methods for depression, how successful is the United States in treating depression? This health services research question raises some basic epidemiologic queries. How many people suffer from depression? Do they seek treatment, and where? What treatments do they receive? The most comprehensive estimates of the prevalence of mental disorders derive from the Epidemiologic Catchment Area (ECA) Study and the National Comorbidity Survey (NCS), which estimated the 1-year prevalence of major depressive disorders at 6% to 7%. The vast majority of depressed individuals (about 80%) contact a health care provider over a 1-year period, but only about 25% receive any appropriate treatment for depression. Most patients (about 80%) who visit a health care provider for depression see a primary care provider; only about 20% of patients with depression visiting a health care provider see a mental health specialist. Among such patients with a treatment contact for depression, 80% of those treated in primary care

Telegram: @medical_k

www.konkur.in

received no appropriate treatment for depression (pharmacotherapy or counseling). The opposite prevailed in mental health treatment settings, where most patients (nearly 90%) received an appropriate form of depression treatment. Such data illustrate the challenges in providing quality care for individuals with depression. Most persons receive no depression treatment (despite some contact with a health care provider). Most of those who do receive some treatment receive inadequate care. The predominant opportunity for the treatment of depression is in primary care. How can clinicians and administrators address these problems in access to and quality of depression care? How can mental health services research assist in these efforts?

Health services researchers have examined interventions targeting providers (the supply-side of care), individuals affected by depression (the demand-side), and policies. By far, the majority of health services research in this area has focused on the supply-side through attempts to change provider management of depression, especially primary care providers, who see most of the patients with depression. Such research has approached the under-treatment of depression in primary care with different interventions of interest. For example, a multicomponent health care system–level intervention called “collaborative care” structures depression treatment in primary care settings by using case managers who educate and follow patients, track outcomes, and adjust treatments for patients who are not responding, consultation and decision support for primary care providers by mental health specialists (psychiatrists or psychologists), and the use of technology-based resources to support the system. Numerous randomized controlled trials on collaborative care for depression have demonstrated meaningful effects on depression symptom improvement, adherence, response to treatment, remission, and recovery from depression, as well as satisfaction with care. However, only a small effect has been established on patient quality of life, including functional status.

A second health services research approach has studied the implementation of quality improvement (QI) programs for managed primary care settings with the goal of increasing the percentage of clinically depressed patients receiving appropriate depression care by national guidelines. The QI intervention consists of four components: institutional commitment of in-kind resources, training of local clinical leaders to implement interventions (cognitive behavior therapy,

Telegram: @medical_k

www.konkur.in

pharmacotherapy), training of local treatment staff, and patient identification. In one 12-month study, depressed patients in QI intervention clinics were more likely to receive counseling or medications, visit a mental health specialist, have a remission from the depressive episode, and retain employment than depressed patients in “control” clinics. Researchers have evaluated another approach in “behavioral health labs” that improves screening and detection of depression in primary care settings. All three of the above depression treatment models demonstrate the potential for improving depression care in primary care settings through “supply-side” interventions. Major challenges remain, however, in promoting the widespread adoption of these approaches.

Far less research on depression care has been conducted on demand-side interventions with patients, although one can certainly argue that even the predominantly supply-side interventions just reviewed increase demand by educating patients about their symptoms of depression and about the value of treatment. Negative attitudes about depression and its treatment among the general population can deter persons from seeking help. Such negative attitudes arise from personal health beliefs, social norms, and stigma, as well as from prior negative experiences with help-seeking. True demand-side interventions are aimed at directly increasing the likelihood that individuals with depression will seek and participate in effective treatment. Such demand-side interventions focus on awareness of the signs and symptoms of depression, self-assessment for these signs and symptoms, the effectiveness of treatment, and skills in seeking help. Some common examples of such efforts include National Depression Screening Day campaigns, free depression screenings at employee health fairs, free pamphlets in physician offices and clinics, antistigma campaigns through the media, and direct-marketing media campaigns on depression, such as those currently put forward by pharmaceutical companies. Health services research that examines the effects of such programs remains sparse, and little is known about the effects of these types of demand-side interventions.

A third domain of intervention to improve detection and treatment for depression in primary care is that of policy, system organization, and financing approaches. A prime example of this type of intervention is the current effort to promote health insurance parity for the treatment of mental disorders. Inadequate insurance coverage for the treatment of a mental disorder poses major barriers to treatment. The federal Affordable

Telegram: @medical_k

www.konkur.in

Care Act (ACA) enacted in 2010 expands coverage of mental health and substance use disorders by including benefits for such disorders in the Essential Health Benefits required of all new small group and individual market insurance plans and by applying federal parity protections more broadly, requiring insurance plans to cover treatment for mental health and substance use disorders at parity with medical and surgical benefits; a projected 62.5 million individuals will benefit by access to these federal parity protections. In addition, the ACA provides states a new option for organizing care in their Medicaid programs: “health home” services for Medicaid beneficiaries with severe chronic conditions who can benefit from enhanced coordination and management of physical and behavioral health care as well as long-term community-based services and supports. The “health home” model aims to improve the quality of health care and the patient experience while providing more cost-effective care. Health services research on service organization and financing seeks to answer critical questions about the effects of policy interventions such as parity laws and “health homes” on issues including the quality and experience of behavioral health care—such as depression care—delivered through reorganized systems.

Case 2: Services for Families of Persons with Schizophrenia

During the second half of the 20th century, clinical research on families in the treatment of individuals with schizophrenia dispelled early assertions that disturbed family relationships play a major role in the etiology of the disorder. Instead, research led to the recognition that families provide major support networks for most persons with this disorder and that they need education and support to enable them to engage as partners in care. The potential advantages of engaging and educating families optimally were suggested by early studies linking high levels of “expressed emotion” among families to a greater likelihood of patient relapse after hospital discharge. Research spanning from the 1970s to the 1990s clearly established family psychoeducation (FPE) as an evidence-based practice in the care of individuals with schizophrenia. The Schizophrenia Patient Outcomes Research Team included FPE as a treatment recommendation, stipulating that patients who have ongoing contact with their families should be offered a family psychosocial intervention that lasts at least 9 months and includes education, support, and some training in problem-solving skills. Other statements of best practices also include a

Telegram: @medical_k

www.konkur.in

recommendation for FPE. FPE was found to reduce relapse rates, improve medication adherence, reduce symptoms, and improve functional outcomes for individuals with schizophrenia. Specifically, more than 30 randomized clinical trials showed that relapse rates for individuals receiving FPE were 25% to 50% lower than those observed for individuals receiving standard individual services.

In line with the health services research framework (see Fig. 56.4–1), investigators have examined the prevailing patterns of practices as they relate to families with regard to both access to any services and, more specifically, access to evidence-based practices consistent with the FPE model. A variety of studies conducted in community settings and in Veterans Administration facilities has shown that not only is FPE rarely offered, but in fact, a far lower standard of family contact with clinicians occurs in the majority of cases. Chart reviews, clinician interviews, and consumer interviews all have produced the same conclusions. Thus, major problems in the access to and quality of family-oriented services exist.

Following the health services quality-of-care framework, researchers have undertaken efforts to improve practices by disseminating FPE. Supply-side approaches have been the most common. Numerous initiatives to disseminate FPE have been attempted throughout the country. The New York State Office of Mental Health (OMH) mounted an impressive effort to implement programs at 35 different sites throughout the state and provided extensive training. Although numerous family groups were started and the potential benefit was large for those families and patients who participated, OMH decided not to continue the project because only a small number of families and patients throughout the state actually received the program. The Substance Abuse and Mental Health Services Administration included FPE as part of an effort to disseminate evidence-based practices by creating toolkits that include informational resources for all stakeholders, a workbook for practitioners, and a fidelity scale. The implementation phase of this project resulted in a limited selection of FPE as a practice to disseminate and limited penetration of FPE in those sites that selected FPE.

The marginal success of these dissemination initiatives for this evidence-based practice demands a greater understanding of how to influence changes in practice. Research must strive to understand and overcome observed roadblocks to the dissemination of family services,

Telegram: @medical_k

www.konkur.in

whether these roadblocks exist on the supply-side among providers and service systems or on the demand-side among patients and their families. Such roadblocks can take many forms. In identifying such barriers, health services researchers seek critical points for intervention to improve dissemination. For example, practitioners may be unaware of the value of the intervention, or they may lack the skills to deliver it. Families may be suspicious of such services as a result of unpleasant experiences based on older family therapy models. Payment systems may not provide support for the programs. However, even the FPE demonstration projects that had the capacity to overcome most or all of these barriers failed substantially to affect dissemination. In such a case, health services researchers have at least two other strategies at their disposal. The first is to develop more inventive dissemination strategies. The second is to decide that a modified or new evidence-based practice is needed—one that is more acceptable to providers, patients, and service systems.

This first task of developing more inventive dissemination strategies requires reevaluating the barriers to dissemination. Such barriers exist at the disparate levels of patient and family, providers, administrators, and payers. Supply-side strategies, such as providing higher rates of reimbursement for providing FPE, as well as more intensive and targeted training for providers, could be successful. Health services researchers investigate these strategies by using qualitative methods to interview providers and payers where FPE initiatives have already been started to determine whether they think that increased rates of payment or training would help. Strategies under study also target barriers to FPE at the consumer and family levels, thus focusing on developing the demand for FPE. A new approach called Recovery-Oriented Decisions for Relatives' Support (REORDER) uses a shared decision-making process to structure patients' exploration of whether they want to include families in their mental health care. REORDER is personalized by attending to patient preferences for family involvement, focusing on the mental health recovery goals of the patient, and exploring how family members could join with the patient to meet those goals. The REORDER clinician begins by working with the consumer to identify the pros and cons of family involvement and then uses education, support, and decision-making exercises to assist and empower patients to meet their goals. A randomized trial showed that this approach markedly increased rates of

Telegram: @medical_k

www.konkur.in

family contact with clinicians while it also increased a measure of recovery among participants assigned to the REORDER condition.

The second strategy to address difficulties in implementing FPE is to develop new evidence-based practices or to test revised models of FPE that attempt to reduce barriers to implementation. For example, a meeting of family researchers and practitioners identified the need to determine the critical ingredients of FPE so that a simpler and briefer model could be tested. The National Alliance on Mental Illness (NAMI) Family to Family Education Program may provide a second approach. This program is not a clinical service but is peer-driven. Trained family-member volunteers teach this manualized 12-week program in weekly 2- to 3-hour sessions. The program provides information about mental illnesses, treatments, medication, and rehabilitation. Participants also learn self-care, mutual assistance and communication skills, problem-solving strategies, and advocacy and develop emotional insight into their responses to mental illness. Although the program does not aim to reduce patient relapse, it may provide some benefits to families. Notably, the program had been widely disseminated in spite of the dearth of systematic research demonstrating its effectiveness. After its dissemination, a partnership between health services researchers and NAMI conducted three sequential studies, including a randomized trial have provided evidence that the program is helpful to families—in improving family functioning, coping, empowerment, and knowledge. This demonstrates that in the pursuit of dissemination of evidence-based practices, health services researchers may tackle the challenge of conducting research on existing practices that are in wide use but as yet relatively unstudied.

Case 3: Addressing the Burden of Mental Illness and Mental Health Disparities Using Technology and Implementation Science

Burden and Treatment Gap. Since the 1990s, we have been aware that mental and substance use disorders (henceforth, mental health and/or disorders) are the largest contributor to the global burden of disease everywhere. This problem will persist as long as a minority of individuals with mental and substance use disorders never receive treatment. This treatment gap is vast and global. In high-income countries, 35% to 50% of people in need of mental health care do not receive care. Despite being home to more than 80% of the world's population, low- and middle-income countries have less than 20% of the world's mental health

Telegram: @medical_k

www.konkur.in

resources. On average, only 0.5% of national health care budgets in low- and middle-income countries (vs. 5.1% in high-income countries) are devoted to mental health care, and 75% to 85% of those with mental disorders in low- and middle-income countries have no access to care. Mental health disparities exist everywhere, and the majority of those in need of mental health care worldwide lack access to high-quality mental health services. Stigma, structural discrimination, human resource shortages, fragmented service delivery models, and lack of research capacity for implementation and policy change contribute to the current mental health treatment gap.

Shortage of Humans Resources/Task shifting. One of the most significant challenges in decreasing the mental health treatment gap is the significant scarcity of trained mental health workers in health care systems worldwide. The shortage of certified mental health specialists is vast and global, especially those who are skilled in using evidence-based practices. “Task-sharing or task-shifting”—the process of delegation whereby clinical tasks are moved from a highly specialized workforce to less specialized health workers, including trained lay health workers—is an effective strategy to deal with the mental health personnel shortage and is a great option to enhance efficiency on delivery of health care services. Multiple studies throughout the world have proven that lay health workers can effectively provide evidence-based treatment for common mental disorders. Task sharing requires a significant, ongoing role for psychiatrists and psychologists to properly train, continually supervise, ensure quality assurance, and support for the nonspecialist health workers.

COVID. Globally, the already limited access to mental health services has worsened as health care systems prioritize COVID-19 care. People with mental disorders are highly vulnerable to Coronavirus 2 (SARS-CoV-2) infection and vice versa. History of psychiatric illness is a risk factor for COVID-19 infection, hospitalization, and death. COVID-19 survivors have elevated rates of depression, anxiety, psychosis, PTSD, mania, and sleep disorders. It has exacerbated the structural, social, economic, health, and mental health vulnerabilities of disadvantaged populations both in the United States and globally (e.g., racial/ethnic minorities, migrants, and displaced people, low socioeconomic background), placing them at

Telegram: @medical_k

www.konkur.in

elevated risk for COVID-19 and its consequences, including increased mental health service needs.

Telehealth became necessary to protect providers and patients against SARS-CoV-2 infection and maintain ongoing care for patients already receiving care or new patients. However, health care systems struggle to make these transitions in providing care. Developing remote-based methods to triage and provide mental health services became crucial. Importantly, wherever this became available via phone or internet, patients previously in care with access to resources and digital infrastructure were more easily adherent to care, as some of the limitations to access to care could be addressed (e.g., travel, childcare, work, school). Unfortunately, the mental health services access for new patients or those without resources was negatively affected. The COVID-19 pandemic calls for a new model of mental health service delivery in a system that was already incompetent to provide mental health care.

Comorbidity among psychiatric diagnoses is the rule rather than the exception. It produces greater functional impairment and worsens social determinants. Both psychopharmacology and/or evidence-based psychotherapy trials have shown efficacy and effectiveness in high-, middle-, and low-income countries, suggesting that both modalities have promise in expanding treatment for mental disorders where services are scarce. Yet, to date, studies integrating mental health in primary care (e.g., Collaborative care) address one or two disorders through individual-level interventions and show low enrollment of racial/ethnic minorities and underserved populations. Decreasing mental health disparities necessitates sustainably implementing comprehensive mental health services for multiple disorders through community-health systems-policy makers partnerships, which in turn can improve functioning and social determinants and inform new policies.

Technology. Leveraging novel technology to support the implementation and supervision of evidence-based treatments can help meet mental health needs. Digital technology in the mental health sector has proliferated globally. Digital patient and provider-facing solutions can give unprecedented access to high-quality mental health care and can effect scalable, cost-saving, reliable, and sustainable, comprehensive mental health services delivery, especially in low-resource settings, yet they are seldom used with disadvantaged communities and public health

Telegram: @medical_k

www.konkur.in

systems. Digital technology can improve overall cost-effectiveness by strengthening the mental health capacity of existing nonspecialists and supporting task-shifted delivery of high-fidelity evidence-based treatments.

Closing the Gap—Implementation Science. The gap between mental health evidence-based treatment research and practice in real-world communities and health systems is vast; less than half of clinical innovations make it into routine practice. Reasons include the fact that researchers tend to disseminate their work through traditional academic conferences and publications. Further, the research settings where researchers develop and test evidence-based treatments do not reflect the complex, less-resourced real-world settings in which they ultimately must be delivered to have a population impact. Dissemination and implementation science address this research-to-practice gap aiming to accelerate the speed with which translation and real-world uptake and impact of testing, evidence-based treatments occur and improve public health. Meeting the population's mental health needs requires employing implementation science methods to integrate evidence-based treatments into routine practice. Importantly, solutions implemented in low- and middle-income countries can offer innovative options that might be applied to improve mental health services across diverse settings worldwide, including high-income countries.

Two ongoing NIMH-funded studies, one in a low-income country, Mozambique, and another in New York City, address these challenges and needs using a stepped-care approach to improve clinical outcomes—symptoms, functioning, quality of life, among patients with any mental disorder guided by the Proctor's implementation framework. The framework asserts that implementation outcomes serve as necessary preconditions for attaining subsequent desired changes in service or clinical outcomes and that clearly distinguishing implementation outcomes from treatment effectiveness is critical for transporting interventions from research settings to practice. The two studies examine three distinct yet interrelated outcomes—implementation, service, and patient outcomes—to determine the overall system-level impact of implementing stepped-care comprehensive mental health services. Certain implementation factors, such as acceptability, appropriateness, and fidelity to the approach, are more salient early in the implementation process and may be leading indicators of reach, retention, sustainability, and cost, the most

Telegram: @medical_k

www.konkur.in

important implementation outcomes. The extent to which services are safe, effective, patient-centered, timely, efficient, and equitable as they are being implemented ensures the quality of care that fosters better clinical care and outcomes and patients' satisfaction. Ultimately, sustainability is the goal.

Both studies evaluate implementation, service, and patient outcomes using a digital platform, the Mental Wellness Everywhere Digital Training and Services Platform (mWell Everywhere), to create digital patient records, screen for all mental disorders and suicide risk using a validated ultra-brief screening (3 items) and triage (10 items) Mental Wellness Tool (mwTool), and guide task-shifted evidence-based treatment delivery with fidelity while monitoring clinical, services and implementation outcomes, and tracking individual and community-level social determinants. The instrument developed in Mozambique combines valid measures and has been tested elsewhere to comprehensively assess all psychiatric disorders and the severity of the illness to guide triage and treatment. The 3-item screener with proxy respondents detects any mental disorder among household relatives, thus allowing for further community reach. This permits efficient and convenient community assessment—an informant can identify with three questions the need to assess a family member living in the same household. Me-Well meets COVID-19 safety requirements (e.g., telehealth); and provides psychosocial support, self-help, and guidance to communities and providers. Using Me-Well, patients with common mental disorders (depression, anxiety, PTSD) receive Interpersonal Counseling, four structured sessions designed for use in nonspecialist settings, and focusing on the relationship between interpersonal problems (e.g., disputes, life changes, grief, loneliness) and the onset of psychiatric symptoms. For patients with severe mental disorders, providers use a tablet-based Medication Diagnostic Algorithm to deliver psychopharmacologic treatment according to specific diagnoses. For treatment of patients with substance use disorders, providers use Screening, Brief Intervention (Motivational Interviewing), and Referral to Treatment (SBIRT), a brief, one to four–session therapeutic approach that employs empathic listening to explore patients' goals, resolve ambivalence, and elicit motivation to change. Patients with moderate to high risk of suicide work with the provider to develop a suicide Safety Plan Intervention (SPI) that includes identifying warning

Telegram: @medical_k

www.konkur.in

signs, coping strategies, and sources of support to alleviate a suicidal crisis when hospitalization is not clinically indicated.

All of these evidence-based treatments have mobile applications that guide facilitators in standardized treatment steps and allow remote monitoring of patient outcomes and treatment fidelity. The Me-Well Everywhere platform guides and supports providers using interactive methods, knowledge tabs with tips and sample scripts, and automated processes to enable both supervisors and providers to recognize clinical “red flags” or fidelity issues. Meta-data from the platform tracks treatment fidelity and individual provider platform uptake implementation outcomes, for example, number of patients seen, the degree to which key activities are completed, and the average number of sessions per patient. Any user data that appears to deviate from the standard sequence of activities is automatically flagged for the supervisor to intervene and provide corrective feedback to the provider. The platform generates a detailed clinical record after each encounter and can communicate with any Electronic Medical Record platform to enable access to patient characteristics and medical needs (e.g., pregnancy, multimorbidities, current medications).

Implementing Me-Well Everywhere in Mozambique will expand the current mental health system that currently only provides access to care to the 30% of the population living in urban areas. In New York City, like in many high-income countries, shortages in mental health resources and how services are rendered create long waiting periods with the ultimate expectation of ongoing rather than evidence-based, time-limited treatment, requiring expansion of human resources to increase access. In reality, more than half of patients who are able to access mental health services drop out of care after 3 to 6 sessions, unrelated to symptomatic improvement. Thus, can we meet people where they are and provide indicated and tested treatment within that brief time frame by using short-term, evidence-based treatments, and reassessing the need for more care, and offer sequential treatments accordingly. Evaluating how to provide services with a more efficient approach using sequentially targeted and tested short-term treatments with proper follow-up assessment to determine the need for continued services may inform solutions to increasing access to those in need waiting for care.

Mental health disparities are associated with social determinants and substantial individual, familial, and community-level suffering. The public

Telegram: @medical_k

www.konkur.in

health system is yet to address the population's mental health and social determinant needs, which in turn worsen mental health and functional outcomes at the individual and community level. Systems of care must tackle all mental health disorders, especially when comorbidities are the norm. However, the scarce siloed mental health resources are insufficient to address these mental health disparities. Health care systems require integrating comprehensive mental health services, implementing brief, valid community, and individual screening approaches, and evidence-based treatments with fidelity. Principles of implementation science provide a road map for how to do so sustainably and inform needed policies to address the vast mental health treatment gap globally. Implementation of evidence-based treatments demands expanding the mental health workforce using task-shifting by rigorously training and supervising human resources with diverse training backgrounds. A multilevel transformative integration of evidence-based, comprehensive mental health services stepped-care leveraging rigorous technologies into health systems in partnership with the affected communities and policymakers can meet these challenges, ensure sustainable, comprehensive mental health services with associated policies to decrease mental health disparities, and improve communities' functioning and social determinants.

OVERVIEW

Pressures are mounting to ensure that the fruits of biomedical research translate into treatments and services. Mental health services research has substantial power to both inform and advance this process. In the end, all mental health services research can be summarized in three questions. Do all persons with mental health needs have access to treatment? Is the treatment they receive of adequate quality, incorporating the latest in scientific knowledge? Does the treatment offer good value—that is, good outcomes for the resources expended? These questions are posed by the field in such a manner as to maximize generalizability and to identify subgroup variations and needs. These questions must also be asked within systems concerned with health care equity and social policy to inform clinical care and maximize the benefit to all individuals—the ultimate goal.

Telegram: @medical_k

www.konkur.in

Mental health services research, necessarily interdisciplinary, must consider how social factors, structural barriers, financing systems, organizational structures and processes, health technologies, and personal behaviors affect access to health care, the quality and cost of health care, and ultimately health and well-being. Health services researchers work closely not only with biomedical colleagues but also with investigators from other scientific disciplines (sociology, anthropology, psychology, economics, education, and political science) and with service system and policy leaders to implement and evaluate changes.

Much of biomedical science tends to be occupied with internal validity—the strength of the claim that the experimental manipulation causes the outcome. This leads to the desire to control all potentially confounding variables, but it reduces external validity. External validity, or generalizability, lies at the center of the translational process and health services research. At the same time, generalizability encompasses sensitivity to variations among subgroups of patients, taking into account demographic and cultural differences in disease, health care beliefs, and behaviors and access, as well as how health systems address barriers and leverage facilitators of services implementation.

Moving forward, mental health services research faces several challenges. First, while the advance of “evidence-based practices” embodies the principle of translating scientific knowledge into practice, more attention must be given to the complementary principle of “practice-based evidence.” In essence, how can one inform the directions of science through evidence that emerges from clinical practice and experience? Second, challenges for treatment systems and for researchers seeking to identify and promote “best practices” arise from the growing diversity of U.S. culture. Third, the field needs a better understanding of how to implement system changes and disseminate best practices. For this, the field must look beyond the traditional medical and social sciences to such disciplines as marketing science. Fourth, research designs that treat service providers as research subjects require careful consideration to ensure the protection of human subjects that have not been traditionally addressed by institutional review boards.

Finally, major challenges exist in the juxtaposition of the comparatively slow progress of science with the needs of practitioners, planners, administrators, and policymakers, who must respond quickly to the needs of patients and systems of care. The Recovery After an Initial

Telegram: @medical_k

www.konkur.in

Schizophrenia Episode (RAISE) project of the NIMH provides a current example of a multidimensional partnership serving to hasten the translation of scientific findings to practice. The NIMH funded two RAISE projects to study the effectiveness and implementation of evidence-based, coordinated specialty care programs for young adults experiencing the onset of nonaffective psychosis. Attention to policy and practice while these research studies were being conducted led to the relatively rapid expansion of resources for evidence-based programs as part of the mental health block grant in 2014. For health services research to remain relevant, new models of partnership will continue to be needed—models that provide timely information in an iterative and collaborative manner among all stakeholders.

56.5 The Psychiatric Hospitalist

ANGEL CIENFUEGOS, M.D.

The "psychiatric hospitalist" model has been adopted for over a quarter of a century by the American healthcare delivery system and other systems around the world. As opposed to the nonhospitalist traditional models, these are medical providers who are part of inpatient programs in medicine, pediatrics, surgery, and now mental health in which the medical care is provided. The hospitalist is a specialist in inpatient treatment based in an inpatient facility or hospital. This type of practice specializes in acute and serious illness rather than chronic ambulatory medicine and health maintenance. They are knowledgeable about comorbidities in acute and critical clinical presentations. The number of hospitalists has grown consistently, and it has been suggested that the generalist who cares for patients across the full continuum of care may be a vanishing breed.

Traditionally, patients had been cared for in the hospital by their prior primary care physicians, in most cases family practitioners or general internists in a "Continuity of Care" model. Over the past several years, hospitalized patients' care is now more likely to be provided by a hospitalist. In especially complex cases that require multiple consultations with subspecialists, it is the hospitalist who coordinates care. When the patient is discharged, they return to the care of the primary care physician and routine follow-up by other medical specialties. This change parallels the change of practice patterns in psychiatry, in which, in many instances, a separate psychiatrist may care for a patient while admitted for inpatient treatment. Historically, these individuals in psychiatry have been called unit directors or ward chiefs of large state mental institutions. However, in their current role, they are the psychiatric parallel of the hospitalist found in medicine and pediatrics. In both cases, outpatient physicians relinquish the care of hospitalized patients to inpatient specialists.

The development of the hospitalist model has occurred similarly for medicine and psychiatry in the context of the changing role of acute care

Telegram: @medical_k

www.konkur.in

hospitals. As both medicine and psychiatry become more ambulatory in orientation, inpatient institutions have moved away from their central role in health care. They have become specialized institutions for acutely ill patients. Generally, the level of severity of illness in the inpatient setting has continued to increase as well as the number of comorbidities. Although the hospitalist model was widely accepted previously in Canada and the United Kingdom, the first modern hospitalist program was established in the United States in 1994, overcoming the opposition of many primary care physicians who objected to the model because of the disruption in continuity of care. In any case, it was a fact that inpatient care had become an economically inefficient use of their time.

The hospitalist has emerged in response to the increasing complexity of care associated with hospitalized patients. These individuals, with time and training, develop significant experience with acutely ill patients. They develop an understanding of continuity and coordination of care since part of their responsibility is to work on the "hand-off"—the patient's transition from outpatient to inpatient and, after treatment, back again to the prior outpatient physician.

The initial growth in the number of hospitalists occurred because leaders at health maintenance organizations (HMOs), some hospitals, and medical groups believed that they would lead to a reduction in inpatient costs without a reduction in patient satisfaction or quality of care. Reduced residency work hours contributed to the growth of hospitalists as hospitals' need for more on-site physicians grew. Recent estimates indicate that the current number of hospitalists in the United States is nearly 30,000. In 2010, 57% of U.S. hospitals had hospitalists on staff, including 87% of hospitals with a number of beds equal to or above 200. Around 80% of VA hospitals currently have hospitalists. Membership of the professional organization for hospitalists, the Society of Hospital Medicine, is about 6,000.

Because hospitalists have become common at the major teaching hospitals in the United States, they have also become a major provider of instruction to medical students and residents in internal medicine and pediatrics. These two groups now receive much of their inpatient education from hospitalists working in their role as attending physicians.

THE DEFINITION OF HOSPITALIST PHYSICIANS

Telegram: @medical_k

www.konkur.in

Hospitalists are defined as physicians who have general inpatient care as the primary focus of their professional activities, which include clinical care, teaching, research, or administration. Hospitalists typically spend more than 25% of their time working in hospital settings. Commonly they are internists taking the place of primary care physicians in providing inpatient care. In addition to patient care responsibilities, many hospitalists become involved in clinical-administrative tasks. Commonly these include quality improvement efforts and peer review. Academic hospitalists may explore issues such as outcomes research that explores the cost and quality of inpatient care. Many lead the development of new inpatient educational programs for house staff and medical students. Most hospitalists work in community hospitals; a smaller number work in teaching hospitals. In those academic settings, their responsibilities expand to include teaching medical students and residents.

In general medicine, most hospitalists have been trained as internists. There is no separate training program for hospitalists, although some residency tracks and 1-year fellowships have begun to emerge. Such residency tracks typically focus on training in inpatient medicine in addition to hospital-oriented quality improvement, patient safety, and end-of-life care. Fellowships usually focus on providing future academic hospitalists with the research skills they will need in areas related to inpatient care.

Hospitalists are usually salaried physicians with defined work hours. They care for patients with complex medical illnesses rather than the chronicity found in outpatient practice. Many of them have interests in health systems and want a chance to improve the quality of services and control costs associated with inpatient practice. The increasing complexity of medical care demands greater specialization. In many settings, it is increasingly regarded as unrealistic to expect physicians to have expertise in both inpatient and outpatient medicine. Supporters of the hospitalist movement emphasize the benefits of a specialized knowledge base. Hospitalists specialize in inpatient care, allowing primary care physicians to focus on ambulatory care. A consequence of the increase in the number of hospitalists has been a proportionate increase in the number of “office-only” physicians as well.

Hospitalists in academic settings are on-site experienced physicians. Their presence helps hospital wards to run more smoothly and, by doing so, increases patient and nursing staff satisfaction. Such individuals are

Telegram: @medical_k

www.konkur.in

usually familiar with the ward dynamics. They also usually have a good relationship with the ancillary staff, appreciate their contributions, and have long-term commitments to the hospital. Such involvement facilitates the management of clinical situations to prevent them from evolving into significant problems. Such individuals also usually have a breadth of clinical knowledge and experience from working in hospitals and are skillful in the expeditious treatment of the seriously ill, comfortable in managing multiple minor inpatient problems, and familiar with consulting various medical and surgical specialists. These attending physicians are also best positioned to provide the supervision that interns and residents need when managing acutely ill inpatients. Due to their inexperience and rapid turnover, interns and residents benefit from the support that a responsible physician provides when making major medical decisions.

It has been suggested that the minimum amount of inpatient work expected of a hospitalist is 25% of their practice. This minimal amount allows the hospitalist to become experienced in the management of common inpatient conditions. Relationships with care providers in affiliated disciplines can also develop more easily with this degree of availability. Such individuals are also more likely to become committed to improving the hospital by participating in quality improvement efforts and helping to control costs.

There are two common models of hospitalist care. The most common consists of full-time inpatient physicians who practice as a group. In the second model, a group of physicians rotate responsibility for inpatient care. The rotational periods vary, depending on the practice of the group. This method allows a group to maintain skills in both inpatient and outpatient practice. It can, however, produce frequent periods of discontinuity in outpatient care.

An additional aspect of the hospitalist model is whether it is voluntary or involuntary. In some managed care organizations, the outpatient physician is required to transfer care to a hospitalist when the patient is admitted for inpatient treatment. Commonly under this model, the outpatient physician is not permitted to write orders and is relegated to visiting the patient in the hospital. In contrast, many physicians voluntarily transfer responsibility for the care of their patients to hospitalists, cardiologists, or specialists in intensive care medicine. For example, it is common for primary care physicians to transfer care of their patients to intensivists (physicians specializing in intensive care) when their patient is admitted to the

Telegram: @medical_k

www.konkur.in

intensive care unit (ICU). In a similar manner, geriatricians working in nursing homes commonly transfer care to internists when their patients are admitted to the hospital. Although not all hospitalists may have the same degree of interest or ability in studying patient outcomes or developing practice guidelines, most of them participate in these creative activities.

ROLES OF THE HOSPITALIST

The predominant role of the hospitalist is to take care of hospitalized patients. Over the years, inpatient care has become more complex and specialized, and while the number of hospitalized patients has decreased, the acuteness of their conditions has risen. Simultaneously, the scrutiny of the length of stay (LOS) and associated hospital costs has increased. It is common to see hospitalists involved in projects to reduce the LOS and cost of admission. Generally, reports show that inpatient care of medical patients by hospitalists reduces LOS and hospital costs. Hospitalists are able to respond rapidly to changes in a patient's condition because they tend to be readily available and are able to expedite the timing of treatments and consultations.

The hospitalist is also the receptor for inpatient admissions. Increasingly, outpatient physicians prefer to transfer hospital care to a specialist. Common reasons for this preference include the convenience of uninterrupted outpatient work, the convenience of not making rounds in the hospital, and a lack of expertise or comfort with the acuteness of illness and clinical skills associated with inpatient work. There is also some desire to avoid the intensive scrutiny associated with providing care to hospitalized patients. Similarly, hospitalists provide pre- and postoperative medical care to surgical patients. Their availability allows the surgeon to be in the operating room all day and ensures that the patient receives appropriate medical care. Many health care systems are having hospitalists become the physician of record for nonmedical inpatients with medical comorbidities.

An analogous situation has long existed with ICUs. Most ICUs are closed, meaning that they use dedicated critical care physicians who accept the patient from the generalist on the ward and transfer care back to them when the patient leaves the unit. These physicians have the skills,

Telegram: @medical_k

www.konkur.in

abilities, and availability to care for critically ill patients, and because of these skills, they have improved outcomes and efficiencies.

In many specialties, including critical care, oncology, bone marrow transplantation, cardiology, infectious diseases, and psychiatry, the hospitalist model is common. The attending physician is dedicated to the inpatient service. In academic centers, this may be for multiple rotations throughout the year or full-time.

An additional role for hospitalists is providing physician participation in hospital management. Commonly this occurs by their joining in quality management operations, the development of hospital policies and procedures, management of the formulary, participation in credentialing activities, and utilization management.

When considering the role of hospitalists, it is useful to realize that they also care for outpatients, often in a consultative role. Some hospitalists participate in follow-up clinics in which patients are seen once or twice following discharge. Such outpatient activities, however, represent only a small fraction of their time.

Hospitalists also play a role in communication. Most systems expect the hospitalist or their designee to contact the primary care physician within 24 hours of admission and to ensure that either a summary letter or the discharge summary is sent to the outpatient clinician at discharge.

Another key role for hospitalists in communication is in the transmission of clinical information from the outpatient care physician to the inpatient provider on hospitalization and the subsequent transfer of information back to the outpatient care physician by the hospitalist on discharge. This “hand-off” is symbolic of the transfer of clinical responsibility that occurs during hospitalization. The hospital-based physician assumes responsibility for diagnosis and management. For this reason, most hospitalists believe that there is an obligation to validate the diagnosis. This is, in essence, the provision of a second opinion about the diagnosis and subsequent management. Much has been written about the hand-off. It is one of the two controversies of the model (the other controversy being the obligatory use of hospitalists). The disadvantage of the hand-off is obvious: important information can be lost and result in discontinuity. There may also be patient dissatisfaction because of the assignment of a new physician.

The hand-off can also be viewed as producing one of the strengths of the hospitalist model. It results in the patient being under the care of a

Telegram: @medical_k

www.konkur.in

physician in the hospital throughout the day. This individual reacts to clinical data in real time. They are the coordinators of inpatient care. However, some surveys show that patients are at least as satisfied with the care from hospitalists as they are with care from their primary care physician. The data suggest that patients may be willing to trade familiarity for availability. It is also noteworthy that many hospitalized patients do not have primary care physicians, especially among the uninsured. In some systems, when hospitalists are introduced, there is an increase in patient satisfaction with their outpatient physician, suggesting that the improved ability to focus on their outpatients is a benefit of this model for the primary care physician.

Hospitalist systems that focus on inpatient–outpatient communication have fewer difficulties. Commonly, programs fax the discharge summary to the outpatient clinician on the day of discharge. Some programs fax daily progress notes as well. Increasingly, programs have a continuity clinic in which patients may be seen once or twice soon after discharge to ensure stability before the patient reappears at the primary care physician's office.

THE PSYCHIATRIC HOSPITALIST

It could be argued that psychiatry was the first of the medical disciplines to adopt the hospitalist model on a large scale. Of interest, however, full-time inpatient psychiatrists have never called themselves hospitalists. Psychiatric hospitals and asylums date back to the early Middle Ages. Until the rise of psychoanalysis, the most widely available career opportunity available to doctors treating the mentally ill was working in a hospital. The choice of career was to work in a publicly supported state mental hospital or a private psychiatric hospital. The physicians then resembled what we would consider to be hospitalists.

In the twentieth century, the advent of antipsychotic drugs led to the trend of deinstitutionalization. Psychiatry, together with numerous other disciplines, adopted the model of continuity of care, in which physicians follow their ambulatory patients in outpatient settings and while hospitalized in the event of a needed inpatient stay.

As the field has expanded and the effect of third-party payers has restructured the profession, the proportion of hospitalists has declined while the absolute number has increased. One of the earliest surveys of

Telegram: @medical_k

www.konkur.in

career areas for psychiatrists dates to 1953; it noted the role of psychiatrists working full-time in hospitals. Later surveys noted that the percentage of psychiatrists working in mental hospitals was decreasing. In 1965, for example, about 30% of psychiatrists worked in hospitals, but by 1979 this had dropped to less than 14%.

One of the problems that nonhospitalist-based psychiatrists encountered was that admitting and caring for hospitalized patients was very disruptive to their careers as outpatient clinicians, academicians, teachers, and researchers. The role of unit director or ward director has been a traditional role in psychiatry. At one time, these individuals were relatively junior psychiatrists who, in academic settings, attempted to succeed in the traditional “triple threat” role. That is, they pursued success in research, patient care, and teaching. In any setting, academic or not, these individuals are the epitome of the psychiatric hospitalist. Their job functions are highly congruent with the descriptions of hospitalists noted earlier.

In 2010, a hospital part of the Veterans Affairs Healthcare System transitioned its mental health inpatient units from nonhospitalist or continuity of care (nonhospitalist based) to a hospitalist-based model of care. This change resulted in an increase in the total number of discharges and a decrease in the number of readmissions within 30 days. Patients discharged by hospitalists were more likely to follow up with after-care appointments.

From a financial standpoint, psychiatric healthcare delivered by hospitalists decreases the LOS and the cost. It also facilitates the care of patients with medical comorbidities since medical consults are readily available, and hospitalists can easily coordinate care with hospitals’ medical and surgical disciplines. In turn, psychiatric hospitalists provide psychiatric consultation to medical and surgical units, reducing those specialties’ cost of care.

Psychiatric hospitalists are familiar with the assessment and treatment of the most severely mentally ill patients, including patients with acute psychotic agitation and patients who attempt to harm themselves or others. They manage patients whose psychiatric illnesses put them in physical danger, such as patients who are suicidal or engage in self-injurious behaviors. They are comfortable with protocols to manage delirium and to assess and treat withdrawal from alcohol and other substances.

Telegram: @medical_k

www.konkur.in

Psychiatric hospitalists also have extensive training in the legal requirements for involuntary detention and involuntary medication administration, and they frequently testify in judicial evidentiary hearings. Civil commitment statutes vary across states, and psychiatric hospitalists are familiar with the statutes for their state, including the requirement for civil commitment hearings within a specified time and the rights of the detained person. For example, some states give detained patients the right to refuse treatment, while others do not. Psychiatric emergency hold laws vary in length from 23 hours to 10 days across the United States, and psychiatric hospitalists know the criteria that must be met for the initial emergency hold and for psychiatric holds to be extended. Psychiatric hospitalists spend most of their time in inpatient units. They carry a significant share of resident and medical student training. Trainees working with hospitalists are frequently more satisfied with the amount of time and dedication they get from their attendings, which normally are part of the clinical faculty of the associated academic institution. These faculty members are expected to be educators in addition to clinicians and are not subjected to the same publication and funding expectations of research faculty. The inpatient units are the center for education and training during the first years of residency and offer the appropriate diversity of clinical presentations providing students with the appropriate amount of learning material.

Psychiatric inpatient units are environments where multidisciplinary approaches involving psychiatrists, nurses, psychologists, social workers, caseworkers, substance use counselors, and, as needed, medical consultants from other medical disciplines. Due to the multidisciplinary nature of inpatient hospital work, psychiatric hospitalists are able to treat medical comorbidities more effectively and are well-qualified to assess appropriateness of transfers from medical to psychiatric units.

HISTORY OF THE MODERN HOSPITALIST MOVEMENT

Several factors have led to this practice pattern. For outpatient clinicians, the arrangement frees them from the disruptive burden of seeing a small number of inpatients. It allows them to focus on their area of expertise: outpatient practice. It avoids the disruptions in the outpatient schedule that can occur when inpatient rounds are a daily responsibility. For the hospital

Telegram: @medical_k

www.konkur.in

and third-party payers, the model reduces inpatient expenditures with similar clinical outcomes. This model does not adversely affect patient satisfaction with care or trainees' satisfaction with their educational experience. Although this practice pattern may benefit hospitals or group practices, its professional fees are not usually sufficient to make the program self-supporting. To remain viable over the long term, such programs require support from the programs such as hospitals or group practices that receive benefit from the efficiencies that these programs produce.

The traditional model for inpatient care was outpatient physicians who made hospital rounds early in the morning and again at the end of the day. There could be calls from the emergency room or the hospital. The calls would, at times, interrupt outpatient practice and interfere with the efficient treatment of outpatients. Many clinicians noted a decline in office productivity when they were obliged to make hospital rounds for a small number of inpatients.

A significant factor that led to the development of hospitalists was the desire to focus efficiently on outpatient treatment and allow inpatient treatment to be provided by those who would give it full-time attention. This allows outpatient physicians to avoid the frequent interruptions, paperwork, and preauthorizations associated with inpatient care.

The acuteness and diagnostic complexity of inpatients have been increasing for the last several decades. At the same time, new and more complex treatment modalities have emerged in inpatient care. Those who only infrequently care for inpatients have found it increasingly difficult to remain current in these treatment methods. Part of the appeal of the hospitalist movement has been that it frees outpatient physicians from the responsibility to remain current with treatments they would only rarely use.

In England and Canada, the early recognition of the benefits of focusing on either ambulatory or inpatient care led very early in this process to the concept of distinct outpatient and inpatient physicians. The term "hospitalist" was first used in the United States by Wachter and Goldman to describe the concept.

In academic medical centers, hospitalists have become a third career pathway in addition to the prior pathways of clinical educator and clinical researcher. The development of the clinical educator had been due to the need to care for outpatients and to teach students and residents at ambulatory care sites. How an individual physician spends their time is

Telegram: @medical_k

www.konkur.in

highly variable and tends to depend on the needs of the institution and the skills and experience of the individual physician. Time is typically divided among providing direct care to outpatients, supervising students and residents in providing ambulatory care, and various scholarly activities. Many also spend several months each year attending an inpatient unit, during which time outpatient responsibilities are reduced. Educational activities may include responsibility for specific courses in the medical school curriculum or the teaching of specific knowledge or skills, for example, the patient examination. Most academic medical centers expect their clinician teachers to do scholarly work to meet standards for promotion. These activities commonly include developing new educational programs, writing review articles or case reports, conducting research, and presenting original work at scientific meetings.

In Europe and Canada, there have long been specialists in inpatient general medicine who have been active in urban hospitals. A clear demarcation between inpatient and outpatient practice is new in the United States. In the United Kingdom, the consultant physician would take over care from the general practitioner when the patient was admitted to the hospital.

The increasing use of such hospitalists was initially spurred on by the emphasis on efficiency that came with the rise of managed care. The managed care environment stimulated the development of the hospitalist model in the United States. The emphasis on efficiency and cost containment took precedence over continuity of care.

Up to the 1970s, most primary care was provided by a general practice physician who was not board-certified in any particular specialty. Most medical care at that time was provided in a hospital setting. In the inpatient setting, the general practitioner was often assisted by the internist, who was often more experienced in inpatient medicine. By the 1980s, family practice had emerged as a specialty and came to define the general practitioner. The role of the internist in inpatient practice was diluted by the rise of medical specialists who could assist the general practitioner with inpatient care. Until the mid-1990s, hospitalists were uncommon in general medicine in the United States. Rare examples of hospitalists in the United States before the 1990s were called house doctors, hospital rounders, or inpatient managers. By the 1990s, however, general internists and family practitioners had begun to focus on outpatient care and had a progressively smaller role in inpatient care.

Telegram: @medical_k

www.konkur.in

Internists began to manage inpatients, and intensivists emerged to manage ICUs. Emergency departments began to be staffed by specialists in emergency medicine.

Although multiple forces were responsible for this change, two major factors were predominant—cost pressures on hospitals and physicians and the increasing acuteness of inpatients. The shift of most medical care to the ambulatory setting resulted in most physicians having little ongoing experience with inpatient care. Practice effects meant that those who did large volumes of inpatient care had superior outcomes.

Many felt that the hospitalist model conflicted with the traditional notion of a generalist who would treat patients in both inpatient and outpatient settings and, in so doing, provide treatment that was less fragmented and more holistic.

THE STAGES OF HOSPITAL CARE

It has been suggested that hospital care in the United States has gone through four stages. In the first stage, all inpatients were cared for by their primary care physicians. This worked best when the acuteness of illness was low, most practitioners had large numbers of inpatients, the cost was not as important as it is today, and hospitals were adjacent to practitioners' offices.

The second stage occurred when these conditions no longer existed. Specifically, hospitals are no longer nearby, the acuteness of inpatients is significant, costs are managed, and inpatient care has a significantly higher degree of complexity. Furthermore, outpatient offices are busy due to the shift of care from inpatient to ambulatory. At this point, physicians may form a group to rotate responsibilities for inpatient care. This system introduces an inpatient–outpatient discontinuity. The compensation for this is the enhanced availability of the inpatient physician.

A third stage is the development of voluntary hospitalists who are dedicated inpatient physicians paid by the hospital, medical group, or managed care company. Under this model, not all inpatient care is provided by hospitalists. Primary care physicians retain the opportunity to manage their patients when they are admitted to the hospital.

A fourth stage is the mandatory hospitalist stage. At this point, all inpatients are cared for by hospitalists. This model is most common when there is strong institutional control of physicians. When there is a loose

Telegram: @medical_k

www.konkur.in

affiliation between the hospital and primary care providers, the relationship is more likely to be at stage three if outside physicians wish to retain control of their patients.

BENEFITS FROM THE USE OF HOSPITALISTS

Many studies of hospitalists have demonstrated a reduction in the cost of care without a change in the quality of care. Hospitalists are more efficient at hospital resource utilization than physicians who spend the majority of their time practicing in ambulatory settings. Many factors are believed to contribute to the improved efficiency of hospitalists. These include the practice effect of being familiar with common inpatient conditions and being more familiar with the hospital system. They are also more available to acutely ill patients and may respond more promptly to changes in their clinical state or changes in laboratory data. Through a rotating on-call system, a hospitalist is on-site at the hospital at all times.

Ambulatory care physicians experience a significant benefit from the presence of hospitalists. Hospitalists allow outpatient-based clinicians to attend to their patients without the disruption in their schedules that can result from the unpredictable demands associated with caring for acutely ill patients in the hospital. Furthermore, many ambulatory care-based clinicians may lack the familiarity with the inpatient management techniques that they had when they were trainees.

For the typical internist, the inpatient census is small. However, this small number of patients typically requires more effort than in the past because the patients tend to be more acutely ill and their care more complex. The pace of hospital work has also quickened, and physicians are under pressure to minimize the LOS. Adding to these challenges is the fact that many conditions that were once an indication for inpatient admission are now commonly treated in the outpatient setting, whether that be the office, the home, or the nursing home. The result is that outpatient practice is also more acute and busier, making the disruptions of providing care for some inpatients also more challenging.

Because most primary care physicians spend decreasing amounts of time caring for inpatients, many feel they have lost some of their skills in inpatient care. This reduction has occurred both because fewer patients are admitted and because the LOS is shorter than in past decades. With fewer inpatients, there are fewer interruptions in a tightly scheduled day of

Telegram: @medical_k

www.konkur.in

outpatients. What emerges is an increasing split between inpatient and outpatient practice.

Hospitalists reduce inpatient resource utilization, resulting in a shorter LOS and a lower cost of inpatient care without a reduction in quality of care or patient satisfaction. The reduction in resource utilization probably is a practice effect combined with the ready availability of hospitalists for diagnostic and management decisions.

The rapid increase in the number of hospitalists in the United States suggests that there are significant benefits to this position. In terms of patient care, their presence in the hospital and ability to be available on short notice allows patients to be managed rapidly. Their availability permits them to assess patients frequently and to promptly follow up on test results. This is thought to be one of the significant factors in how hospitalist care produces a reduction in LOS. Hospitalists may also shorten a patient's stay in the emergency department by being available throughout the day to admit a patient. An experienced hospitalist usually becomes comfortable caring for acutely ill patients with a variety of medical conditions. In some cases, this may result in a decreased use of laboratory studies and consultative services. This may also contribute to a reduction in the cost of inpatient care.

There are a large number of uninsured patients in the United States. When they present in the emergency department seeking admission, there usually is no primary care physician with whom they have a prior relationship. Therefore there is no outpatient physician available to manage their inpatient care. An increasing role for hospitalists is to provide care for these patients.

An additional benefit of the hospitalist approach is the ability of outpatient physicians to dedicate themselves to outpatient care without the distractions and interruptions of acute inpatients. Many office-based physicians feel that providing inpatient care is not cost-effective. The poor reimbursement for hospital visits is a common reason that many no longer provide hospital care. Outpatient physicians are also increasingly seeing sicker patients. Their volume of inpatient work has also increased. Due to these factors, many physicians feel that it is increasingly important to focus on improving their availability and skills in ambulatory medicine. These goals are facilitated by focusing exclusively on outpatient medicine. Inpatient medical care is increasingly complex. Due to this increasing complexity, inpatient care requires a higher degree of specialization than

Telegram: @medical_k

www.konkur.in

in the past. For this reason, it is increasingly difficult for physicians with limited inpatient practices to maintain their expertise in inpatient care. Good communication between inpatient and outpatient physicians also has enhanced the acceptance and perception of the benefits of this model. A key aspect of communication is the prompt delivery of a discharge summary to the outpatient physician.

In all areas of medicine, there has been a shift away from relatively healthy individuals with acute illness being admitted to the hospital toward individuals with increasing levels of medical complexity. The hospitalist is increasingly seen as the specialist focused on the medically complex inpatient. Due to their training and experience, these inpatient physicians become proficient in the efficient management of acute illness. Commonly patients are hospitalized because they are profoundly ill or suffer from a rare or atypical illness. They benefit from their hospitalist's inpatient skills.

Hospitalists also work with surgeons to provide primary inpatient care to surgical patients in the pre- and postoperative periods. These combined hospitalist–surgeon teams have been associated with reductions in postoperative complication rates with no significant difference in cost or LOS.

Hospitalists improve the efficiency of inpatient care while maintaining or enhancing the quality of care. Their expertise comes from familiarity with the management of common inpatient conditions. Efficiency consists of reductions in resource use, usually measured as the average LOS and hospital cost. This occurs because hospitalists are familiar with clinical pathways, are experienced in the planning of postdischarge care, and are available throughout the day to respond to changes in diagnostic data or clinical conditions.

Hospitalists relieve office-based physicians of the unpredictable demands of hospital practice. Patients are no longer kept waiting, and physicians no longer have the inconvenience of recurrent trips to the hospital. Outpatient physician productivity increases following the removal of inpatient responsibilities. Outpatient physicians are more reliably available. They are not interrupted by hospital calls or the need to abruptly leave to see acute inpatients. They are able to expand their outpatient hours because they no longer make inpatient rounds. Their workday is more predictable.

Hospitalists standardize the quality of inpatient care. In many academic medical centers, there has been a concern about the wide variation in

Telegram: @medical_k

www.konkur.in

inpatient abilities found in community-based clinicians. Many programs have worried about granting these physicians admitting privileges or opportunities to participate in the teaching service. When a hospitalist system is used, it allows both the community-based physicians and the outpatient academic faculty to enjoy the same quality of inpatient care that is provided by hospitalist faculty.

Hospitalists produce clinical science with an emphasis on outcomes research, quality assessment, and quality improvement; clinical trials to improve treatment or diagnosis; and the development of clinical guides and pathways.

There is a positive correlation between experience and quality of care in a number of areas of medicine and surgery. When implemented, the hospitalist model has resulted in fewer but more appropriate specialty consultations, lengths of stay, and hospital costs. From familiarity, hospitalists develop good working relationships with ancillary hospital staff, including discharge planners, nurses, consulting specialists, and outpatient physicians. Retention and recruitment improve in the hospitalist system.

HOSPITALISTS AS CLINICIAN-EDUCATORS

Large academic institutions are the leaders in hospitalist-based care. In these institutions, one of the hospitalist functions is the training of residents and medical students. Some are considering or implementing hospitalist fellowships. This means house staff receive training from those with expertise in hospital care. There is an expert readily available throughout the day to confer with about patient management. There is improved teaching and expert guidance. Hospitalists provide role modeling to trainees for careers in hospital work.

The effect of hospitalists on academic medical centers may further the separation between researchers and clinicians. The researchers will further focus on research and obtaining grants. The clinician-educators will concentrate on clinical work and teaching. With the group of clinician-educators, there will be a further subdivision, with some focusing on outpatients and others on inpatients.

Hospitalists also improve the educational experience for medical students and house staff. Because the faculty supervisors are skilled and experienced in modern inpatient care, they provide more effective

Telegram: @medical_k

www.konkur.in

teaching and oversight. Generally, when academic programs have evaluated the teaching abilities of hospitalists, there has been enhanced satisfaction by students and residents when compared to prior models. Some trainees have also noted a reduction in workload associated with the hospitalist model. House staff report that hospitalists are more effective at teaching than general psychiatrists.

Many academic medical centers have hired hospitalists as clinician-educators. This need has arisen because primary care physicians are able to spend very little time in the hospital. This results in less time with trainees for educational activities. The expectation is that hospitalists will devote more time to education, performance feedback, and supervision.

Resident evaluations of teaching by hospitalists are higher than those of traditional attendings who briefly rotate onto the teaching service.

Clinical research done by hospitalists has traditionally consisted of studying the hospitalist movement. This included studies of the efficiency, cost, and quality of hospitalist-run services, including inpatient–outpatient communication. Research has begun to expand to include prevention of nosocomial infections and hospital quality assessment, including medical error and pain management, health services and outcomes research, and ethics. Newer areas also include clinical trials that focus on conditions common to the hospital and genetic epidemiology.

DISADVANTAGES AND OBJECTIONS TO THE HOSPITALIST MODEL

There are two potential models for the hospitalist system: Voluntary and closed. In a closed system, only hospitalists have admitting privileges, and ambulatory care physicians are excluded. An open system allows both groups to admit their patients. Concerns have been raised that a closed system may engender bad feelings among community physicians.

A potential disadvantage of the hospitalist model is that outpatient physicians will lose their skills in treating inpatients (although some have questioned how serious a disadvantage this may be if they are no longer providing inpatient care). It is clear, however, that by focusing on outpatient care, they can be expected to improve their skills in that area.

Subspecialist consultants may be apprehensive that hospitalists, due to their familiarity with common inpatient conditions, may produce fewer consultations. A reduction in consultations would be associated with a

Telegram: @medical_k

www.konkur.in

lower cost of care. Because of the severity of illness in hospitalized inpatients, consultations will continue to occur.

During the transition from outpatient to inpatient and again with the transition back to outpatient status, there is a risk of poor communication between the treating clinician and the receiving clinician. With appropriate phone calls and copies of discharge summaries and letters, it is possible to minimize this problem and avoid a significant loss of medical information. An aspect of this coordination of information flow is the risk of fragmentation of care and the loss of a care coordinator who has comprehensive knowledge about the patient's health. In addition, the discontinuity of care and associated lapses in information flow may be associated with a higher risk of medical error.

An additional issue is that the number of acute care hospitals is diminishing, and with them, so is the relative percentage of patients admitted to the hospital.

Implementation of the hospitalist model has an effect on the roles of other physicians operating in the hospitalist system. Hospital-based specialists typically serve as consultants to admitting physicians. Because hospitalists, due to their increased experience, are more familiar with common inpatient conditions, their need for specialty consultations is less than that of nonhospitalist admitting physicians. This has an effect on the volume of consults and the income of consultants.

Generally, residents have been happy with the quality of teaching provided by hospitalists, ranking them higher than traditional attendings. However, because of their greater expertise in patient work, it can also be expected that hospitalists will threaten the autonomy of residents. They tend to have an increased physical and intellectual presence on the wards.

Discontinuity of care is a consequence of changing physicians when moving from the outpatient to the inpatient setting. The associated concern is a gap in information about the patient's wishes and clinical state during the transition. The outpatient clinician loses care of the inpatient, and the hospitalist loses follow-up care when the patient is discharged. This discontinuity is often addressed by hospitals by developing programs to enhance communication. These efforts commonly include the prompt calling of outpatient clinicians on admission and discharge and faxing discharge summaries.

Telegram: @medical_k

www.konkur.in

Evidence suggests that patients accept hospitalists without significant difficulty. Generally, they are satisfied with the quality of care and do not perceive significant differences between hospitalist care and that provided by their outpatient clinician or traditional ward attendings. It has been suggested that patients may be willing to trade the familiarity of the outpatient clinician for the enhanced availability of their hospitalist. It has also been suggested that patients may no longer be as emotionally bound to their physicians. Many patients have no regular outpatient physician. Furthermore, in the current insurance environment, patients may switch health plans and providers with frequency.

Increasingly, training programs in psychiatry, medicine, and pediatrics emphasize ambulatory care. This raises questions about the adequacy of preparation of recent graduates for inpatient attending. Training programs may need to be revised to provide appropriate preparation for the hospitalist role.

Physicians who wish to provide both inpatient and outpatient care may be unhappy with the hospitalist model. For many ambulatory physicians rotating responsibility allows physicians to maintain inpatient care skills. Some ambulatory physicians are uncomfortable with the potential loss of these skills.

PROFESSIONAL ORGANIZATIONS

The National Association of Inpatient Physicians is a nonprofit organization founded in 1997. It is dedicated to advancing the practice of inpatient medicine and promoting excellence and efficiency in clinical care. It is affiliated with the American College of Physicians. There is no analogous professional organization for psychiatrists.

SPECIALTY TRAINING AS A HOSPITALIST

Increasingly, training programs are geared toward providing only enough inpatient training so that graduates are capable of caring for acutely ill outpatients. Special tracks may be developed to provide adequately trained hospitalists. These programs would focus on developing clinician-teachers with the skills and knowledge necessary for inpatient practice. Sufficient outpatient experience would be provided so the hospitalist would comprehend what level of severity can be managed in the

Telegram: @medical_k

www.konkur.in

outpatient clinic. In medicine, tracks exist at both the resident and fellow levels.

As the training of hospitalists becomes common, one emerging possibility is the development of two types of residencies. One would emphasize ambulatory care, and the other would focus on hospital-based care. This would evolve through the use of different tracks for residents. In psychiatry, this separation would be expected to occur after the first two years, which usually emphasizes inpatient and consultative work.

FINANCIAL, POLITICAL, AND ORGANIZATIONAL ISSUES

In many hospitals, the reimbursement for inpatient care is such that revenues from hospitalist services are insufficient to provide for the costs of physicians to staff the hospitalist program. In many cases, the benefits to the hospital or, in the academic medical center, to the training program are sufficient to justify additional program support. In academic programs, the training and service obligations are often thought to justify the additional cost.

The willingness of ambulatory care physicians to forgo inpatient care has been heavily influenced by the relatively low compensation. Many have realized that they can increase their clinical income by substituting relatively higher-paying outpatients for lower-paying inpatients and avoiding the unreimbursed commutes to the hospital.

However, it is the low rate of reimbursement for inpatient care that complicates the implementation of the hospitalist model. Low reimbursement along with a payer mix that often includes uninsured patients means that few hospitalist programs can support themselves solely on professional fees. Further complicating the picture is the fact that clinicians are reimbursed a single professional fee each day despite commonly interacting with the patient several times a day and also working with allied professional staff and families. The net result is, commonly, a significant shortfall in the revenue needed to pay hospitalist physicians at a rate commensurate with community norms for other physicians. Generally, hospitals are able to generate about 60% to 80% of their salaries by fee-for-service billings and/or capitation dollars. Because of the benefits they provide to hospitals, practice groups, and other

Telegram: @medical_k

www.konkur.in

sponsoring agencies, these groups commonly supplement the shortfall in professional fee income.

The hospitalist model will have an effect on a hospital's income. Cases that are paid on a per diem basis may produce less income because of the shorter LOS that occurs with hospitalist attendings. In a capitated case rate in which the hospital is paid according to diagnosis-related groups or when a medical group is paid on a contract rate, there are clear benefits from the reduced lengths of stay and reduced use of ancillary tests associated with hospitalist attendings. In such situations, the savings that result from the use of hospitalists may exceed the salary support provided by the institution. This significant savings is the rationale for supporting the salaries of hospitalists.

To avoid the perception of a conflict of interest, most institutions avoid paying hospitalists to reduce the utilization of services. However, many programs have created incentives related to outcomes measures and patient satisfaction.

HOSPITAL MEDICINE AS A NEW SPECIALTY

Fellowships are currently very limited. Typically they focus on training clinical educators and provide a curriculum on teaching theory, curriculum development, and evaluation methods and opportunities to strengthen teaching skills, along with opportunities to receive feedback about teaching activities. Some also provide instruction on research methods and encourage clinical research activities.

In many institutions, hospitalist positions are staffed by recent graduates and are intended to be transient. In these settings, the opportunities for long-term career development are unclear. In contrast, academic settings that intend to develop a stable cadre of hospitalists provide protected time for promoting scholarly activities and working on improvements in the hospital system.

Traditionally academic medical centers have been challenged in attempting to recognize the contributions of clinician-educators. It is these accomplishments that are the basis of being rewarded with promotion through the professorial ranks. Customary measures of accomplishment include publications and grants, along with other objective evidence of regional, national, and international recognition. The challenge has been to apply these assessment standards to the provision of clinical care or

Telegram: @medical_k

www.konkur.in

teaching ability. Traditionally, teaching capabilities have been assessed by peer and student evaluations. More challenging is the assessment of clinical excellence.

Hospitalists, similar to emergency medicine physicians and critical care specialists, are site-defined specialists. That is, their area of expertise is not defined by an organ or procedure but by where they deliver care. As such, they care for patients with a variety of illnesses and ages within that location.

In medicine, there are other attributes associated with a subspecialty. There is a large group that identifies themselves as hospitalists. There is a professional society with regular meetings. There is a clinical textbook. Clinicians agree that there is a core skill set and body of knowledge.

FUTURE DIRECTIONS

The hospitalist movement is rapidly growing in psychiatry, medicine, and pediatrics. In the latter two areas, where the numbers are more clearly known, the number of hospitalists is larger than those in many board-certified subspecialties. The hospitalist movement, similar to prior trends in emergency medicine and critical care medicine, has a defining environment and a correspondingly separate body of knowledge and skill set.

Hospitalists can be expected to have an increasing role in improving care for hospitalized patients. Due to their extensive familiarity with the workings of the hospital, they are able to identify system problems and help both hospital workers and staff in dealing with stressful situations, including catastrophes, pandemics, and others. They are able to work with administrators and nurses to ensure that necessary equipment is available and proper protocols are in place to facilitate quality care.

Hospitalists have developed related research areas. Typically these are outcomes-oriented studies that focus on hospital care. Examples include quality of care, cost containment, resource utilization, and LOS. Such studies are typically conducted by academic hospitalists at university medical centers.

The digital health movement is changing healthcare across all disciplines, and hospitalists are likely to contribute to the enhancement of electronic health records (EHRs), particularly to ensure their reliability and portability to outpatient providers. While documentation in EHRs can be

Telegram: @medical_k

www.konkur.in

time-consuming, ultimately, EHRs improve hospital care by providing clear and reliable documentation, in contrast to the hand-written notes of the pre-digital era. Since these EHRs are often accessible to outpatient clinicians, EHRs also facilitate continuity of care.

Currently, the term hospitalist does not refer to a subspecialty. In medicine, there is a growing effort to make the hospitalist a subspecialty with residency requirements and board certification. The future may see similar trends in psychiatry.

Unresolved questions about the future of the hospitalist movement remain. For example, should hospitalists be exclusively inpatient providers, or should there be some component of outpatient or consultative work? Should all inpatient care be delivered by hospitalists, or is there also a role for outpatient clinicians in the inpatient setting? How will hospitalists be compensated, and who will employ them? What is the optimal training to be a hospitalist?

As the acuteness of inpatients increases, the demands of the job increasingly resemble emergency medicine department attendings or intensive care specialists and are less like outpatient primary care clinicians. Whereas current compensation for inpatient and outpatient physicians is similar, it can be expected that compensation for hospitalists will also increasingly resemble that of intensivist or emergency medicine physicians.

Unique to psychiatry, there is a certain lack of recognition of the hospitalist physician as a differentiated area of practice. In other areas of medicine, the hospitalist role is widely recognized. Despite a long history of the hospitalist role in psychiatry, a role that dates back to the origins of the profession, few psychiatrists who work predominantly in a hospital setting would consider themselves to be hospitalists. They are more likely to call themselves unit directors, ward directors, or attending physicians. As the recognition of psychiatric hospitalists increases, a further appreciation of the similarities and differences between psychiatric hospitalists and hospitalists in other areas of medicine can be expected. One can expect, for example, that the activities of colleagues in other areas of medicine will provide guidance for improving the career path for hospitalists, starting with fellowships and progressing through various levels of seniority following training.

Under-recognized and poorly characterized, psychiatric hospitalists can be expected to be at the forefront of interactions with third-party payers

Telegram: @medical_k

www.konkur.in

that seek to alter the nature of psychiatric hospitalization. Improved recognition of their role, clarity of their training pathway, and identification of the stages of professional career development will promote this career pathway to trainees and ensure that there are well-trained individuals providing expert inpatient care.

56.6 Psychiatric Rehabilitation

Lujain Alhajji, M.D., Vanessa Padilla, M.D., and Radu V. Saveanu, M.D.

Telegram: @medical_k

www.konkur.in

Mental illness represents one of the leading causes of disability, with depression being a major cause of disability worldwide. Serious mental illness (SMI) results in severe significant impairment in functioning. Psychiatric rehabilitation can have a dramatic impact on improving functioning, independence, recovery, and integration in society. The field of psychiatric rehabilitation continues to grow and evolve. While initially thought of as a series of psychosocial interventions that were aimed at augmenting psychopharmacologic approaches, it has now become collaborative, integrative, multi- and interdisciplinary. Multidisciplinary care ensures that patients' biologic, psychological, and social factors are recognized and interlinked. Patient-centered approaches are imperative in reaching personal recovery outcomes.

For a successful outcome of psychiatric rehabilitation, a patient-centered, holistic, and strength-based approach needs to be implemented. A comprehensive understanding of the patient's psychiatric conditions, treatment regimen, social support, contextual cues in the environment, and individual strengths and limitations needs to be incorporated.

Psychiatric rehabilitation is intended for people living with severe mental illnesses (SMIs) such as schizophrenia, bipolar disorder, or schizoaffective disorder, as well as for those with treatment-resistant major depression, severe anxiety disorders, and substance abuse (alone or as comorbidity). Desired long-term outcomes should involve increased autonomy, subjective sense of well-being, financial independence, and improved quality of life in addition to focusing on remission and symptom control. Many persons with schizophrenia may achieve control over positive symptoms, such as hallucinations and delusions, but still have to deal with negative symptoms that impact communication, initiative, and interpersonal interactions. Neurocognitive symptoms of schizophrenia have been implicated in reduced ability to function in the home, workplace, and community. However, these cognitive effects extend well beyond issues with memory, processing speed, and executive dysfunction. Indeed, some of the greatest difficulties with community functioning are related to deficits in social cognition, including perception and processing of affect, knowledge of social rules and conventions, inferring another person's intentions, as well as attributing causality for positive or negative outcomes. For example, people living with schizophrenia may struggle with inferences or attributional biases. Lack of

Telegram: @medical_k

www.konkur.in

insight into one's own processes and misinterpreting the emotions and intentions of others can lead to isolation, limited meaningful interpersonal contact, difficulties dealing with others in the community, and problems with interacting with others in the workplace.

Psychiatric rehabilitation strategies are increasingly holistic, integrative, respect the autonomy of the individual in decision-making, and specify incremental, graduated goal attainment with the goal of optimal function in the community. Functional outcomes and improved quality of life remain important aspects of psychiatric rehabilitation. Providing integrative and early psychiatric rehabilitation services that incorporate mental health, substance abuse, and medical health care service delivery can ameliorate the burden of disease, reduce symptomatology, increase employment and productivity, and improve the overall sense of well-being.

PSYCHIATRIC REHABILITATION IN THE MEDICAL SETTING

People living with SMI have an overall poorer health condition than the general population, with a higher prevalence of common conditions including cardiovascular disease, metabolic syndrome, and HIV. They are also at a higher risk of comorbid substance use disorders (SUD), most commonly nicotine use, which may further precipitate, worsen, or exacerbate medical issues. Persons living with schizophrenia are more likely to suffer from obesity, and treatment with antipsychotics further increases this risk. In addition, lifestyle and social factors such as poor access to healthcare services, lack of education or access to nutritious food, financial constraints, and lack of exercise can all contribute to poorer overall health. Inflammation may also play a role in elevating risk factors for chronic medical conditions. Moreover, by facing stigma in their personal lives, persons with SMI may be dismissed by healthcare providers who attribute their somatic complaints as psychiatric in nature. Persons with psychiatric disabilities can face barriers in advocating for themselves and communicating effectively with their health providers. General poor health among individuals with psychiatric disabilities negatively impacts their ability to pursue education, gain employment, become financially independent, and be productive members of their communities.

Telegram: @medical_k

www.konkur.in

Psychiatric rehabilitation was previously considered a psychosocial treatment program that focuses on aspects such as social skills training (SST), vocational remediation, and building environmental supports. It is now recognized that many psychiatric disorders need to be conceptualized as chronic conditions with relapses and remissions; hence, psychiatric rehabilitation has also evolved to include psychosocial as well as medical approaches. Persons with SMI may struggle with treatment adherence which can lead to exacerbations of underlying psychiatric, substance use, and medical disorders. As a result, a major focus of many current psychiatric rehabilitation approaches is to facilitate adherence to medical treatments and medication regimens as a primary focus of psychiatric rehabilitation. This is typically achieved by using advanced therapeutic and behavioral techniques. Motivational interviewing is also often used to elicit a patient's ambivalence relating to taking medications as recommended. With growing technologic innovations, the integration of electronic reminders and innovative smartphone solutions such as mobile apps have also expanded. An emphasis on cognitive and behavioral training with regard to prospective memory, or "remembering to remember," an intended action is emphasized to promote medication adherence. Further, it is well accepted that medication compliance is likely going to be higher with concomitant efforts to build a supportive environment by preparing the individual to deal with environmental stressors and promoting a physically and emotionally healthy lifestyle. For example, there is a bidirectional relationship between diabetes and depression, with depressed patients having increased challenges to comply with self-management of their diabetes (glucose monitoring, taking medications, following strict dietary recommendations, and exercising, among others). Collaborative care models shared medical appointment models, and cognitive-behavioral therapy (CBT) for adherence and depression (CBT-AD) are available strategies to assist patients with diabetes to improve their medical care management. Integrating approaches to care requires the coordination of several health care disciplines.

UNIFYING CONCEPTS OF PSYCHIATRIC REHABILITATION AND TREATMENT

Telegram: @medical_k

www.konkur.in

Successful approaches to psychiatric rehabilitation involve the integration of medical, psychological, and psychosocial approaches. As described below, psychiatric rehabilitation is more person-centered and needs to be tailored to individual needs and goals. Collaboration between rehabilitation team members and patients is vital as this enhances therapeutic alliance, partnership, autonomy, and shared decision-making on behalf of providers, patients, and their families. This partnership in shared decision-making takes into consideration the patients' and their families' specific needs, as well as their cultural beliefs and values. This individualized approach to treatment also emphasizes targeted goals that are unique for an individual patient with the appropriate combination of therapies that are specific to the person's needs.

It is of essential importance for both the patient and the treatment team to (a) identify targeted short-term and long-term goals that are operational and obtainable; (b) plan a sequence of interventions and support systems that are appropriate to an individual's stage of recovery; (c) build in social and environmental supports, stress management, coping strategies, and other continuing therapies that will reduce the chances of relapse; and to (d) continue a collaborative treatment milieu between the patient, family, and care providers that provide the greatest opportunity for mutual respect and decision making. Collaborating with the patient as an active participant in their rehabilitation journey means that treatment becomes educational as well as treatment-focused.

PSYCHIATRIC REHABILITATION AND INCORPORATION OF PERSON-CENTERED RECOVERY MODELS

In the United States, the New Freedom Commission on Mental Health (2003) recognized the voices of the recovery movement and mandated that recovery be consolidated into all facets of mental health policy. The person-centered approach was cited as a vital aspect of recovery, as defined by the U.S. Substance Abuse and Mental Health Services Administration (Department of Health and Human Services, 2004). Collaborative, person-centered approaches to care planning are increasingly recognized as instrumental in accelerating personalized recovery goals. Person-centered care core principles include the development of respectful relationships between providers and people

Telegram: @medical_k

www.konkur.in

experiencing SMI; the integration of the person in identifying individualized goals; the significance of involving personal, family, and community-based resources to reach those goals; a recognition of responsible risk-taking as a necessary part of growth and recovery; and a focus on acknowledging the strengths and capacities of the person as an essential step to recovery.

This integrative method requires a multidisciplinary or interdisciplinary team approach. The person-centered approach builds upon this by actively engaging the patient and their family in shared decision-making to cocreate an action plan toward recovery such as medication use and incorporates their personally relevant goals and unique psychosocial circumstances into the formulation of treatment plans. Family involvement may especially be important for individuals from diverse cultural backgrounds who value family input. Family-focused recovery may play a key role for some people living with mental illness, as their individual and family needs may be better understood by the family as a group and incorporated into the recovery plan. Encouraging the individual to actively engage in recovery planning can help them develop the confidence and skills needed to regain control over their lives.

The person-centered approach is in line with a more optimistic vision for the long-term recovery of the seriously mentally ill as it offers opportunities to generate higher levels of motivation in patients. These progressive changes in ideology have mostly been championed through the ongoing leadership of federal, state, and local agencies. Many training programs are more cognizant about teaching emerging healthcare practitioners about the person-centered, recovery-oriented mode of service delivery, which is expected to continue to intensify and develop in the coming years given that this approach is expected to strengthen the therapeutic alliance, promote greater motivation and collaboration, and achieve better outcomes. It is vital to follow the same person-centered approaches with all patients, with a focus on valued outcomes, while also tracking and measuring outcomes of success of services provided over time.

DEFINING RECOVERY

Outcomes of psychiatric rehabilitation can vary given the heterogeneity of SMI and the wide variety of services available. Reaching recovery goals can hence vary based on the patient's own targets, as well as personal

Telegram: @medical_k

www.konkur.in

attributes, social environment, continuity and quality of treatment, and subjective experience.

Sustained recovery is a long-term process and refers to long-term abstinence or remission of symptoms and return to normal psychosocial functioning. Recovery allows persons living with SMI to improve their overall health and wellness, lead self-fulfilled lives, and empower themselves to reach their full potential as contributing members of their community. It can be measured by a set of processes, stages, and outcomes that are based on mediating and moderating variables that facilitate its attainment and maintenance. That is, recovery is an outcome of the process of recovering.

Hope, destigmatization, empowerment, self-acceptance, insight, awareness, collaboration with professionals, sense of autonomy and self-control, as well as participation in self-help and patient-run programs, are all attributes that may help individuals progress toward recovery. Subjective experiences and attributes mediate the process leading to recovery and also sustain recovery. For example, a treatment or self-help program may engender a feeling of empowerment, which can be instrumental in motivating a person to sustain treatment and rehabilitation until recovery can be achieved. Once recovery has been achieved, empowerment may be even more firmly experienced through continuously improved functioning and cognitive, social, and emotional stability.

Many factors can influence recovery, including overcoming and managing one's symptoms, choosing healthy outlets and appropriate treatment to support one's general well-being, having access to healthcare and stable housing, obtaining purpose and meaning from one's life, including having enjoyable daily activities, financial independence, and contribution to one's community, and having supportive relationships. Rehabilitation services must remain flexible in the services provided to individuals and continue to advocate for their patients, reduce health disparities, improve access to care, and ensure that care delivery supports their patient's sustained recovery.

Similarly, having hope for future improvements in quality of life may be reinforced by the enthusiasm and collaborative alliance embedded in a therapeutic relationship. Many patients who have written first-person accounts of their recovery have pointed to the importance of a long-term relationship with a practitioner who refused to give up hope for the patient's ultimate improvement and recovery. Hope can serve to fuel

Telegram: @medical_k

www.konkur.in

motivation for change and for active participation in clinical services or self-help, which are stepping stones toward recovery. Subjective experiences of empowerment and hope continue to grow after a state of recovery is attained, contributing to further strengthening and protecting individuals from stress-induced relapse. Encouragement and hope also enhance efficacy expectations that empower the individual to assume greater control and responsibility for their lives.

EMPIRICALLY BASED MODELS OF PSYCHIATRIC REHABILITATION

Psychiatric rehabilitation has evolved from being considered an add-on treatment if conventional measures with psychotropic medications or psychotherapy fail, to a way to “fill the day” with activities for persons with SMI, with descriptions of the token economy of other reinforcement programs. Psychiatric rehabilitation has moved to become an evidence-based, highly specialized specialty within psychiatry, offering structured interventions, assessment tools, and defined target goals in order to reach desired individualized outcomes in persons with SMI. Evidence-based practice recommendations are based on well-designed research studies that show effective interventions in improving illness course and outcome.

Over 50 years of intervention research has led to the expectation that even patients with the most severe mental disabilities can improve their overall daily functioning when provided with empirically validated, evidence-based behavioral interventions. Some examples of evidence-based practices (EBPs) for the recovery of SMI include assertive community treatment (ACT), cognitive-behavioral therapy for psychosis (CBTp), cognitive rehabilitation, family psychoeducation, illness self-management training, SST, and supported employment, among others. Some other forms of interventions are gaining more evidence, though not yet evidence-based, such as expressive and art therapy in patients with schizophrenia.

In 1991, the Americans with Disabilities Act was signed into law, requiring equal employment opportunities and reasonable employer accommodations for workers with mental illness. Moreover, fulfillment of interventions for therapeutic improvement has been facilitated by political advocacy, destigmatization of mental illness, and self-help activities of

Telegram: @medical_k

www.konkur.in

consumer organizations such as the National Alliance for the Mentally Ill, the Schizophrenia Fellowship, and networks of mental health clients.

Recovery is now more than ever a realistic goal for many persons with mental disabilities with enduring biologic vulnerabilities such as schizophrenia; however, it is necessary that the full range of evidence-based biopsychosocial services be available in a continuous, accessible, comprehensive, coordinated, person-centered, culturally appropriate, and competently delivered system of care. Despite the fact that the field of psychiatry produces a wide array of evidence-based treatments and services, public and private funding has eroded for organizing and delivering these services with high fidelity. With that in mind, psychiatric rehabilitation is confronted with the major challenge of fiscal limitations, inadequate resources, and poor coordination. Two core principles of psychosocial rehabilitation include: (i) all resources allocated to the recovery process should be coordinated and integrated with the goal of optimizing treatment, and (ii) a consistent therapeutic team should provide continuity of care, taking into account the person's life context.

ACCESSIBILITY TO EVIDENCE-BASED TREATMENT AND SERVICES

Despite the growing evidence available on psychiatric rehabilitation, there is a wide gap between the scientific literature and the design and practice of many psychiatric rehabilitation programs. This means that evidence-based psychiatry rehabilitation interventions are not widely available, nor easily accessible, in day-to-day clinical practice. Funding opportunities may be limited and can hinder the development of these programs. In addition, there are many differing opinions among psychiatry professionals in relation to views on recovery and treatment goals, as well as patient and family expectations, which can further prevent the restructuring of existing programs and the new development of quality-based programs.

One of the biggest hurdles in implementing evidence-based rehabilitation programs and improving access is organizational level challenges, competition in allocating funds to resources, a lack of administrative and financial integration of state and local community mental health and substance abuse services, and, at times, a limited understanding of mental health needs beyond symptom control. While the

Telegram: @medical_k

www.konkur.in

United States revolutionized the concept of evidence-based rehabilitation services, it appears that the existing services fall behind other high-income countries. The consequences of those system-wide problems have meant that too few individuals with mental disabilities are receiving state-of-the-art services and too many thousands end up living on the city streets or in jails and prisons.

Implementing recovery-oriented and person-centered programs can take a long time, requiring the commitment of providers to not only practice but also train and educate others entering the field. Conducting continuous measures and tracking outcomes is vital for quality measures. Engaging learning environments, such as training events and user-friendly practical guidelines that support clinical decision-making, can be helpful in training future rehabilitation providers. An example of this includes the development of a free evidence-based resource center from the Substance Abuse and Mental Health Services Administration (SAMHSA), which provides toolkits available on their website: https://www.samhsa.gov/resource-search/ebp. These efforts, such as the project implementing EBPs, have mostly been sponsored by federal, state, and foundation agencies. Standardized guidelines for the application of the evidence-based treatments are provided in workbooks that are included in the toolkits focused on improving the functioning, quality of life, and recovery of patients, as are training materials and procedures to provide means for assuring high-quality treatments.

The American Psychiatric Association (APA) has also provided free-access training materials for psychiatrists on basic understanding of recovery from SMI and SUDs and recovery-oriented care. These training videos can be accessed at https://www.psychiatry.org/psychiatrists/practice/professional-interests/recovery-oriented-care.

The ultimate purpose of any available EBP toolkit—“to promote the implementation of evidence-based psychosocial treatments in routine mental health settings”—is a goal that has great potential to improve the lives of people diagnosed with serious mental health disorders. Access to EBP Toolkit helps clinicians, agencies, and organizations to be educated in facilitating best practices in the training, implementation, and monitoring of evidence-based treatments for mental health. However, implementing and directly monitoring fidelity to the model can be a costly and time-consuming process. A balance needs to be achieved between monitoring

Telegram: @medical_k

www.konkur.in

the accurate implementation of each EBP while promoting its dissemination in a way that allows institutions to tailor the innovation to fit the specific function, mission, patient population, local resources, and other contingencies they face. Continuous quality improvement has been used effectively as an approach to implement EBPs in community-based settings.

At the level of the community agency implementing EBPs, specific expectations for clinician performance and ongoing program evaluation, as well as a culture change, are required to implement and sustain the provision of EBPs. Thus, evaluating the cost-effectiveness of the EBP toolkits using a longitudinal time frame and a methodology that captures the organizational characteristics and the total expenditures to the systems of care in using the EBPs for the patients within their catchment areas is essential to the long-term viability of these programs.

With improved and more reliable diagnostic methods, as well as symptom and functional assessment and an empirically validated definition of recovery, the population and needs of patients requiring psychiatric rehabilitation are becoming better defined. Methods for determining readiness for rehabilitation also have been validated, enabling administrators and providers to be more efficient in allocating rehabilitation programs and resources. Because of its growing technology and its conceptual and empirical base, psychiatric rehabilitation has attracted an interdisciplinary group of practitioners and investigators whose work has contributed to its evolving scope and stature.

The challenges to community-based care for persons with serious and chronic mental illness have been met partially by new initiatives at the clinical and policy-making levels. New interventions have been designed and validated, such as psychoeducational and behavioral family therapies, SST, CBT for medication-resistant psychotic symptoms, intensive case management models for assuring continuing care, supported housing, and employment services. At the level of psychiatric politics, consumers and families have become empowered by the advent of peer-directed self-help organizations; the use of social media for the education of the public about mental health disorders and the possibilities for recovery, including noted political, sports, and entertainment figures going public with their experience of living with mental health disorders and successful treatment; legislative lobbying, assertive advocacy, peer support, and family involvement in treatment; efforts to gain parity in

Telegram: @medical_k

www.konkur.in

funding for mental health services; and the Americans with Disabilities Act regulations.

The COVID-19 pandemic has brought on many challenges in mental health care delivery. Provision of rehabilitative care for persons living with SMI is vital to monitor COVID-19–related recovery outcomes, including the accessibility of services, healthcare disparities, rate of relapses and symptoms exacerbations, rates of telehealth encounters, patient and family satisfaction with the quality of care, functional, social and vocational outcomes.

REHABILITATION IN THE PRODROMAL, ACUTE, AND STABLE PHASES OF SEVERE MENTAL ILLNESS

Effective treatment and rehabilitation of persons with SMI require clinical services that are linked to the phase of their disorder. For most stress-related, recurring, and disabling mental disorders, the following phases are relevant for practitioners' initiating and/or adjusting their treatment:

- Motivation and engagement in treatment
- Prodromal
- Acute
- Stabilizing
- Stable
- Recovery
- Refractory

There is broad-based variability in the manner in which individuals experience a particular phase in that no two individuals experience any phase in the same way. Individual differences influence each phase in terms of severity, duration, degree of disability, resolution, course, and boundaries. The following cases depict two persons in the stabilizing phase. This serves to exemplify the need to adapt treatments to individual diversity within a particular phase of illness.

Telegram: @medical_k

www.konkur.in

Mr. B, a 19-year-old male, was admitted for involuntary psychiatric hospitalization after he locked himself in his room for three days and refused to eat because he was afraid someone was poisoning him. His father would hear him talking and yelling to himself incoherently. When his father was able to enter his room, he found the room to be in disarray with the windows covered with newspapers, as Mr. B thought he was being watched. After six days of stabilization, he was released from the hospital and returned home to his father but was still very anxious about being alone, had difficulties with hearing voices telling him he was "cursed," and was extremely concerned that his movements were being monitored. Because he was resistant to oral medications (he thought they might be meddled with and might poison him), he was prescribed a long-acting injectable antipsychotic, which helped to stabilize his symptoms. Upon returning to school, he completed a semester taking a reduced course load and living at home. However, during the next semester, he insisted on taking a full course load and started to smoke cannabis and other drugs to help manage the resultant distress. He began to feel on edge and felt that others in his class were judging him critically and talking about him. His grades started to deteriorate, and Mr. B developed another acute psychotic episode. He was readmitted to the psychiatric hospital with extreme paranoia and had to again drop out of school. This time, treatment became integrative, and, in addition to adjusting his psychiatric medications, he received supportive psychotherapy and was engaged in several cognitive-behavioral and skills-building training that provided him with ongoing support and structure. He learned to be more assertive and comfortable in his interactions through assertiveness, social skills training, and relaxation/stress management techniques, which greatly helped his coping skills. Mr. B eventually returned to school, earned his degree, and is currently in a supportive work program.

Ms. A, age 24 years, had persistent depressive symptoms that increasingly became worse, particularly when she graduated from medical school and accepted a role as an internal medicine resident in a busy county hospital. She became increasingly convinced that she was an unqualified physician despite graduating with honors and felt hopeless and worthless. She consistently felt that she was subpar compared to her peers, which further perpetuated her sadness,

Telegram: @medical_k

www.konkur.in

hopelessness, and her sense of failure. As a physician intern, she struggled to complete necessary clinical duties due to fatigue and impaired attention and concentration. On top of existing insomnia with difficulty falling and staying asleep, transitioning to night shifts further impaired her sleep. Her husband noticed that she was becoming more isolative, tearful, and was not interested in joining her residency group activities or completing house chores. Her family started to become increasingly concerned about her lack of communication and began to worry about her engaging in self-harm behaviors. Ms. A. started to feel that she was a burden to others and began to think about death. On an evening shift, she encountered a verbally hostile patient who demanded to transfer his care to a different provider. She then became acutely suicidal and was subsequently admitted to an inpatient psychiatry unit for treatment and stabilization of her severe depression. Following discharge from the hospital four days later, she was placed on a combination of antidepressant and antipsychotic medications and immediately referred to a psychotherapist who focused on CBT techniques. It took several weeks before she was adequately stabilized to engage in interventions for major depression and suicide prevention. In addition, Ms. A and her husband started couples' therapy with another therapist that helped the husband better understand her illness, supported her behavioral homework, and helped the couple to communicate better. Ms. A, with the help of her supportive residency program director, is now back to work, with an adjusted on-call schedule, and is involved in maintenance therapy where she sees her psychotherapist weekly and continues to adhere to all her mental health treatment.

FIGURE 56.6–1. Multidimensional framework for phase-linked treatment and rehabilitation.

These two examples illustrate the need to conceptualize the treatment of these two individuals into several components (a) stabilization; (b) dealing with ongoing acutely psychotic, mood, or anxiety symptoms; (c) using the therapeutic alliance to provide the maximum motivation for treatment; (d) using integrative therapeutic support to augment and strengthen the possibility of positive treatment results; (e) ongoing assessment and strategies aimed toward relapse prevention; and (f) reinforcement and maintenance of gains.

The framework for phase-linked treatment and rehabilitation is depicted in Figure 56.6–1. It should be noted that EBPs are the backbone of services generally found to be useful for patients as they traverse the various phases of their disorder. There is considerable variability in how fast each individual moves from one phase to another, and progression may not be linear in fact. Some may even skip a phase, becoming stable within one week of an acute relapse, without the gradual stabilization of symptoms and functioning that is more frequently the case. People also move back and forth between phases as stressors impinge on their

Telegram: @medical_k

www.konkur.in

vulnerability, and the individual has not compiled sufficient protective factors.

Prodromal Phase of SMI

Early identification, engagement, and treatment are the mainstays of this phase, which may be associated with individuals who are at risk of their first episode of SMI or are experiencing the warning signs of a recurrence of their disorder. Preventive interventions for young people at high risk of developing a psychotic illness remain in the early stages of development and need further investigation. Psychosocial and pharmacologic interventions have not been empirically documented as fully effective in averting schizophrenia or other psychotic disorders when provided to young people experiencing prodromal signs and symptoms. The sensitivity and specificity of identifying the early signs of a developing psychosis have not been fully validated; however, recent review studies suggest that "basic symptoms" (defined as 'subtle, subclinical disturbances in one's experience of oneself and the world that prospectively predict first episodes of psychosis') can improve the prediction of psychotic relapse. Further prospective studies are still needed to compare basic symptoms and early signs as predictors of psychotic relapse. Moreover, in the digital era, some studies have focused on social media activity (primarily via patterns of linguistic and behavioral changes) and the use of machine-learning models to identify and predict psychotic relapse in young individuals with recent-onset psychosis and imminent risk of hospitalization.

Youth who are possibly moving toward their first psychotic episode may experience sleep problems, strange, unusual, unwanted, and intrusive thoughts, depression, irritability, hypomania, or anxiety. Other prodromal signs and symptoms include ideas of reference, paranoid worries and fears, significant social and emotional withdrawal, suspiciousness, apathy and loss of drive, disturbances of attention and concentration, functional deterioration, odd behavior, perceptual abnormalities, and derealization. These young people almost always refuse to accept professional intervention, preferring to think that their condition is transient and will dissipate without psychiatric treatment. Moreover, the stigma of mental illness is a major deterrent to obtaining treatment.

For these individuals and their families, a patient-centered, nonconfrontational stance is desirable. Because it is not even certain that

Telegram: @medical_k

www.konkur.in

they are moving to an acute psychotic episode, it is necessary to monitor the presenting symptoms and how they might be interfering with the individual's current life. Then, depending on the specific problems that are interfering with the individual's reaching their goals, the psychiatrist points out that treatment may very well help to overcome the obstacles to progress toward these goals. This approach is known as motivational interviewing and represents a strategy for engaging patients in early treatment. It may be necessary for the practitioner to ally with the family so that the latter can join in the motivational enterprise. The treatment approaches to this early developmental phase of schizophrenia are delineated in Table 56.6–1.

Symptoms Prodromal to a Relapse. Because each psychotic episode places the individual at greater risk of prolonged psychosis, disability, and refractoriness to treatment, prevention of relapse has been assigned a high priority. It is often the case that the individual with recurrent illness does not recognize or acknowledge their symptoms; in this case, it is best to simply work on building a relationship with the patient that will eventually pay dividends for active treatment once trust has been achieved or restored.

Telegram: @medical_k

www.konkur.in

Table 56.6–1.
Interventions for the Prodromal Phase of Schizophrenia in Young Persons Not Yet Diagnosed with the Disorder

1. A psychoeducational approach is directed to the patient, family, other caregivers, primary care physicians, school counselors, and staff at college counseling centers. The psychoeducation must be keyed to the particular needs, readiness, and role of the individuals who are in a supportive relationship with the individual who is experiencing the prodromata to a serious mental illness. Outreach and liaison with "gatekeepers" to mental health services—primary care physicians, clergy, schoolteachers, and school counselors—is important for mental health facilities and solo practitioners to mount a successful effort in identifying young individuals at high risk of a serious mental disorder. There should be ongoing liaison, education, and consultation with the family and referring professionals and agencies.
2. Nonstigmatizing, age-appropriate, culturally congruent services should be offered in a youth-friendly, nonclinical environment.
3. Specific treatment for symptoms and behavioral problems that are interfering with the young person's goals and functioning should be adopted:
   a. Motivational interviewing.
   b. Stress management.
   c. Cognitive-behavioral therapy or interpersonal therapy for anxiety and depression.
   d. Cognitive-behavioral therapy for prepsychotic symptoms.
   e. Supportive relationship that permits open discussion of the young person's concerns, worries, symptoms, and progress toward goals.
   f. Antipsychotic medication at low dose for symptoms that do not respond to psychosocial interventions and continue to impede the young person's functioning.
4. There should be frequent re-evaluation of the patient's clinical status to determine whether a schizophrenia prodrome is actually operating.

If possible, prior to a recurrence of psychosis, the practitioner should provide illness management services that include training in recognizing and monitoring early warning signs of relapse together with developing an emergency plan for preventing full-blown relapse. This educational effort

Telegram: @medical_k

www.konkur.in

is important because recurrent episodes of schizophrenia, major depression, bipolar disorder, and other SMIs carry a poorer prognosis and a higher risk of:

- More frequent acute illness episodes in the future
- Higher likelihood of nonadherence to treatment
- Greater difficulty treating each recurrent episode
- More serious disruption of social, occupational, educational, and family roles
- Greater likelihood of stigma and family isolation
- More frequent involvement of police, involuntary admission to hospital, homelessness, and legal problems or incarceration.
- Increased financial and emotional burden for the family.

Early Intervention and Relapse Prevention. One component of illness management is educating patients and their families to recognize the prodromal signs and symptoms of relapse, monitor them, bring them to the attention of the mental health provider, and follow through with their emergency plan to avert relapse. Early intervention during the initial onset of a psychiatric disorder should be implemented to minimize the risk of developing chronic disability.

An acute episode of mental illness, including relapse for persons who have had previous episodes, frequently follows prodromal signs and symptoms for patients with mood and psychotic disorders. Regardless of where a patient resides during an acute episode of illness—crisis home, family home, inpatient unit, or partial hospitalization—the major task is to mitigate overstimulation and provide a safe, secure, supervised, and predictable environment. This is accomplished by offering clear expectations for daily activities, a posted schedule of daily events, discharge criteria, standards for each privilege level, and a structured routine and treatment environment. Staff experienced in working with acutely ill patients offer individualized, clear expectations for behavior and low task demands that are not unnecessarily burdensome but are flexible in terms of how much social interaction is prescribed. In addition, the staff should offer low-key planned and scheduled activities, orientation, and guidance on the rules of the facility by posting visual aids on the bulletin board and whiteboards. One staff member should be designated to help each patient conduct problem-solving and offer supportive therapy at all hours.

Telegram: @medical_k

www.konkur.in

In this intervention phase, pharmacologic and behavioral treatments of acutely ill patients are intended to stabilize or eliminate symptoms and improve cognitive status so that the patient can move toward focusing on the development of skills and utilizing the social and professional supports that will help the individual move into the next phase of treatment. Close and prompt postdischarge monitoring is vital. Discharge planning should include not only the assessment of psychiatric symptoms but also consist of access to safe housing, outpatient medical and mental health care, employment, community resources, and social support.

Most patients in the acute phase can begin learning illness management skills, including understanding their symptoms, describing their mental illness and treatment plan, and creating strategies for minimizing its impact on their daily functioning and reducing rehospitalizations. During the acute treatment phase, it is essential to customize skills training and support to symptomatic and cognitively impaired individuals; thus, in educating, it is very important to use strategies such as motivational enhancement, repetition, responsive reading, modeling, role-playing, and problem-solving. It is also necessary to be flexible in using relevant and culturally appropriate communication in educating patients about the value of psychotropic medication use.

Continuity of Care From Hospital to Community. Continuity of care with mental health and other medical providers is essential for improving provider–patient relationships and reducing fragmentation of care. It is associated with greater patient satisfaction, higher adherence to treatment, and reduced hospital service utilization. Due to hospital stays becoming shorter than in the past, patients may be discharged with ongoing active symptoms and may not be sufficiently optimized. Despite efforts by hospital providers to ensure continuity of care and create a postdischarge plan, numerous studies have confirmed the frequent lack of follow-up when transitioning from inpatient to outpatient care.

Patients struggling with persistent acute, distressing symptoms postdischarge from inpatient care may face obstacles when attempting to engage in outpatient services. Cognitive deficits are common in SMI and interfere with the patient taking the initiative or planning to set up a follow-up appointment. Psychoeducation with frank and honest discussions should be conducted with the family involved, as at times, the patient's support system may believe that definitive treatment has been completed

Telegram: @medical_k

www.konkur.in

in the hospital, fail to encourage follow-up services, or even suggest discontinuing medications due to lack of psychoeducation or understanding of recovery, as well as the presence of stigma toward mental health care services.

Case managers can help facilitate this transition by coordinating a community mental health liaison to visit the patient while hospitalized to introduce themselves, discuss services, and answer any questions. An outpatient case manager or representative can also accompany the patient to visit their community mental health center for follow-up. This familiarization can reduce anxiety, as the patient will no longer need to repeat their histories which may often be related to traumatic experiences during past acute episodes, and increase the likelihood of follow-up. Providing transportation from the patient's home directly to the facility for their appointments increases attendance and participation.

Training programs, such as the Community Re-Entry Module, empower patients transitioning out of the inpatient psychiatry setting to learn skills and attitudes that support continuity of care. Some of the skills taught include: connecting with the community, planning a daily schedule, making and keeping appointments, and managing medications. These skills allow the patient to take responsibility for making the connection with outpatient services with the purpose of enhancing their quality of life by functioning more autonomously.

In this continuity of care program, family members are involved in the training as much as their schedules permit. A randomized, controlled study comparing the continuity in reaching outpatient services for inpatients who participated in the Community Re-Entry Module versus those who received standard discharge planning by a social worker showed that more than 80% of the individuals participating in the module succeeded in getting to an outpatient facility after leaving the hospital, compared to only 37% of those receiving a standard discharge. This study confirms the capabilities of patients with schizophrenia to take responsibility for maintaining their treatment.

During the acute phase of treatment, some common patient responsibilities include such functional and symptomatic outcomes as engaging in independent self-care and personal hygiene without prompting, socializing with peers without hostility or social withdrawal, voluntarily accepting medication, and learning the reasons why medications are being prescribed—both for dampening the current

Telegram: @medical_k

www.konkur.in

symptoms that led to the hospitalization and for prophylactic purposes to reduce risk of relapse. The patient and physician review the daily behavioral progress, which is the cornerstone of motivation, hope, and shared decision-making. Most inpatient units have “level systems” that are used to provide incentives to patients to take more responsibility for their self-care, reliability, participation, and behavior. Level systems can be customized to meet the individual needs of specific patients by using tokens, credits, or points superimposed on the level system. Another way to motivate patients to reach their goals and discharge readiness during the acute phase of illness is to use therapeutic contracts. Therapeutic contracts invite collaboration in that both parties describe their goals and responsibilities for the inpatient period of treatment.

The psychiatrist and other staff must ensure that the patient is familiar with and has a plan for reaching follow-up care as an outpatient. As discharge approaches, the responsible psychiatrist should reach out to the family and invite them to attend a psychoeducation meeting with the psychiatrist present to answer questions and give feedback on how their relative is progressing. Having the family present with the psychiatrist and treatment team during a psychoeducational meeting in the acute phase of illness provides opportunities to acquire another source of information about the patient’s illness and disability. Family members may be more reliable assessors, and many of them keep written records or diaries of the course of illness, medications, and responsiveness and side effects of the illness. Home visits seldom occur in the current era; however, this can provide considerable information about the quality of life of the patient in their current environment prior to hospitalization, thereby enabling more accuracy and clinical acumen to be brought to bear on the diagnosis, treatment experiences, and social functioning of the patient.

Stabilization Phase

Stabilization of symptoms and monitoring of cognitive deficits almost always continue after acute discharge into the stabilization phase. Most of the considerations noted previously in the acute phase are continued in the outpatient setting; hence, the treating psychiatrist has the responsibility for ensuring that continuity of care is updated.

Once the patient is discharged from the inpatient setting, it is likely that medications are to be continued. Monitoring symptoms using quantitative scales such as the Brief Psychiatric Rating Scale (BPRS), the Positive

Telegram: @medical_k

www.konkur.in

and Negative Syndrome Scale (PANSS), or the Target Symptom Scales during regular appointments can help the prescribing practitioner make informed decisions regarding dosing or type of medication changes. Responsiveness to medication is also affected by the emotional climate in the family, which needs to be considered by the prescribing psychiatrist. The use of a quantitative rating scale for the informed use of medications is illustrated by the stabilization of the patient in the following case, a young woman with schizophrenia.

Ms. C, a 30-year-old woman, had three previous hospitalizations with relapse of acute psychosis, exhibiting paranoid delusions and auditory hallucinations. These symptoms were stabilized with antipsychotic medication. The positive symptoms of schizophrenia were much improved after her last hospitalization; however, she reported having “no interest or motivation” and no desire to interact with others. During the first month of outpatient visits, her psychiatrist gradually titrated up her medication, with evidence of stability in that her delusions and hallucinations remitted. However, serial monitoring with the PANSS indicated worsening in her negative symptoms of schizophrenia. A family meeting revealed that the family did not comprehend the effect that negative symptoms could have on Ms. C’s daily functioning despite the lack of active psychosis. As a result, they criticized Ms. C for not returning to work, leading to frequent heated arguments. The psychiatrist scheduled a series of weekly and then biweekly educational sessions for Ms. C and her parents to explore the family structure, expectations of treatment and provide psychoeducation about Ms. C’s illness and treatment. This intervention gradually lowered the “emotional temperature” of the family household, resulting in Ms. C receiving the assistance that she needed in order to engage in vocational rehabilitation.

During the stabilization phase, learning illness management skills, including gaining a more solid understanding of the role of medication, can be very useful. This includes skills such as how to communicate assertively with the psychiatrist about side effects or lack of symptom reduction, as well as how to communicate with friends and family about their illness. Supportive treatment sessions are provided on a weekly or

Telegram: @medical_k

www.konkur.in

biweekly basis with extended invitations to the family or other caregivers to participate in the training sessions for illness management focusing on proper medication use and relapse prevention.

Illness self-management education involves teaching individuals with SMI about the nature and course of their medical and psychiatric conditions, engaging them in motivational interviewing to explore implementing lifestyle choices that can promote better illness management, instructing them how to monitor their symptoms, how to self-administer medications, and preparing them on signs and symptoms that warrant contacting their treatment providers or seek emergency treatment. Behavioral skills training is useful to address nonadherence to help incorporate taking treatment as prescribed into the individual's day-to-day routine. Developing a relapse prevention plan can be useful to provide a physical, concrete reminder for the patient to monitor their symptoms. Helping the patients develop coping strategies for persistent symptoms can reduce emotional distress.

Collaborative Relationship With Patient. The development of a collaborative and therapeutic relationship is essential if the patient is to remain in long-term treatment and make progress toward their personal goals. Personal, relevant goals are motivating for the patient's participation in the phases of stabilization, stable, and recovery. Depending on the needs and desires of the patient, these goals can be connected to areas of functioning such as self-management, friendship, and intimacy, work or school, family relations, housing, recreation, financial, and spiritual needs. The psychiatrist and other mental health professionals working with the patient must help the patient set incremental, stepwise goals that will bring the patient closer to their overall personal goals.

As symptoms and cognitive impairments stabilize, the patient may benefit from weekly SST that gives the patient opportunities to learn from social modeling, role-play practice, and homework assignments to facilitate achieving short-term goals that are on the pathway to overall goals. For example, a man in his 30s who has reached the recovery phase of schizophrenia may have a personally relevant goal to find an apartment and live independently. With the guidance of the skills trainer, he may proceed through a series of steps, including the following:

Telegram: @medical_k

www.konkur.in

- Learning and demonstrating the ability to engage in medication self-management and other Independent Living Scales (ILS) required for living in an unsupervised residence.
- Through problem-solving training, identifying various ways to locate apartments that are for rent, and generating options.
- Evaluating the pros and cons of each identified apartment—for example, costs, location, and availability of public transportation.
- Practicing in the group how to ask questions assertively about the apartment with the property manager or owner, then applying the skills practiced to real-life situations.
- Reviewing the advantages, disadvantages, and feasibility of each apartment and making a provisional choice with second and third preferences.
- Role-playing in the group session on how to request a loan from parents to help subsidize the rent, then carrying out the request with parents.
- Role-playing in the group session finalizing and signing a lease agreement with the property manager, then doing it in real life.

Once he settles into an apartment, there are many more related goals, including furnishing the apartment, meeting neighbors, and identifying and engaging in social events available in the community. Once the individual is successfully established in the apartment, he may again set new personal goals such as making friends and finding a part-time job.

Increasing motivation through repeated successful reinforcing experiences can encourage the patient to establish broader functional goals and reinforce therapeutic alliance with the rehabilitation team. As therapeutic relationships strengthen, so does the willingness of patients to confide in their treatment team.

Involving Families in Stabilization. Families play a major role in facilitating or impeding improvement in patients with SMI—including schizophrenia, mood disorders, disabling anxiety, or somatoform disorders. In many instances, family members become caregivers for persons living with psychiatric disabilities. Involving family members can help prevent relapse, encourage treatment adherence, facilitate a supportive home environment, reduce distress, and promote a fitting level of patient independence. Through rehabilitation efforts, families can be included in planning, monitoring, and promoting stabilization. In fact,

Telegram: @medical_k

www.konkur.in

mobilizing families as partners in the treatment enterprise is relevant for all phases, including stable and recovery periods.

Relatives and other caregivers can be involved in treatment sessions that are organized either for individual families or multiple family groups, with goals limited to psychoeducation about the nature, course, and treatment of the psychiatric condition or, more extensively, teaching skills in communication and problem-solving, coping with persistent symptoms, managing crises, and implementing relapse prevention plans.

In the stabilization phase, patients should be involved in family sessions as their symptoms and cognitive impairments permit. It is essential that family services be fully integrated with other treatment modalities being offered to the patient, such as social and vocational rehabilitation and medication management. Multidisciplinary integration is accomplished most effectively through regular consultations and interactions among all those responsible for the patient's services. Communication among mental health providers can be initiated and led by the psychiatrist through phone calls, case conferences, team meetings, and virtual platforms. Families can also benefit from participation in educational programs offered by their local National Alliance on Mental Illness (NAMI) affiliates that include Family-to-Family seminars and Homefront meetings for families of veterans, as well as family support groups, educational lectures, and annual statewide and national conferences. For the specific individuals living with SMI, NAMI also offers a free Peer-to-Peer educational program to better understand their illness and their recovery process.

Contact with families should continue indefinitely because they often serve as the most important continuous thread of support that weaves together the various phases of illness. It is now well established that patients living with relatives who learn coping skills from behavioral family management have two to three times fewer relapses than patients who are treated with medication and case management alone.

Stable Phase

Patients are considered stable when their symptoms no longer interfere with their functioning in everyday activities. This does not mean that their symptoms are in remission, although they are usually rated as "moderate," "mild," or "very mild" on the BPRS. Some patients living with schizophrenia, for example, are able to participate in work, school, social,

Telegram: @medical_k

www.konkur.in

and recreational activities in normative settings even when delusions and hallucinations are present on a daily basis. Psychological interventions can displace symptoms, such as when patients are actively engaged in conversations or tasks that shift their attentional capacity from isolated self-preoccupation. Cognitive functioning, such as attention and planning, can also be improved by cognitive remediation (CR) in this phase of treatment.

Incremental steps toward achieving long-term, person-centered goals continue in the stable phase. Progress toward goals can be promoted by participation in training programs that use behavioral learning principles to assure generalization of skills learned in skills-training sessions that take place in clinical settings. The key to generalization is for clinicians, family members, or peers to promote opportunities and encourage, as well as reinforce the use of skills in the natural environment.

Vocational Rehabilitation. Vocational rehabilitation programs exist to bridge the divide between persons with SMI who are interested in working to gain employment. During the stable and recovery phases, patients may be able to begin job-seeking or return to school. Although supported employment (or supported education) is the most popular evidence-based service for vocational rehabilitation, it is not the only occupational goal that is clinically relevant. A wide variety of vocational and educational activities can be compatible with the stable and recovery periods of functioning. Before some patients are ready for work in competitive jobs, they inevitably need to transition through work-related activities short of regular jobs in the community. The Clubhouse Model of Psychosocial Rehabilitation is an example of a model in place for persons living with severe mental illness who engage in a nonclinical, integrated therapeutic working community to achieve recovery by strengthening work-mediated relationships. Studies have found evidence of the efficacy of the Clubhouse Model in promoting employment, reducing hospitalization, and improving quality of life for those with SMI.

At the same time, it is important to recognize the value of supported employment because patients with mental illness who gain jobs in the competitive sector can work half-time or more in competitive lines of work and can gain satisfaction with their renewed or achieved status as workers. Based on direct comparison analysis and network meta-analysis, supported employment and augmented supported employment have been

Telegram: @medical_k

www.konkur.in

found to be the most effective interventions for obtaining and maintaining employment for those living with SMI. Supported employment provides persons with SMI an opportunity to obtain competitive employment through a rapid job search and retention, whereas traditional vocational rehabilitation programs provide a “training-place” prevocational training and experience in noncompetitive, structured staff-supported settings with other SMI individuals prior to work placement. Individual placement and support model of supported employment (SE-IPS) also includes collaboration with psychiatric services, counseling on benefits, and counseling on job challenges such as disclosure of psychiatric illness, transportation challenges, and meeting job expectations.

However, not all individuals with mental disabilities wish to participate in supported employment. Many persons living with SMI show ambivalence toward obtaining competitive jobs. Approximately half of those with disabling forms of schizophrenia, mood disorders, and personality disorders do not engage in supported employment. Moreover, supported employment is not always associated with increased self-esteem, quality of life, global functioning, or reduced psychiatric symptoms. There are alternative ways to lead a working life, including an array of opportunities that can be viewed as prevocational in nature, such as volunteer opportunities and on-the-job training.

Various work circumstances can lay the groundwork for recovery. A 2018 meta-analysis reviewed 21 SE-IPS programs randomized controlled trials around the world and found that participants in SE-IPS programs were more likely to obtain a competitive job compared with alternative vocational rehabilitation services (mean risk ratio = 2.31 [95% CI 1.99–2.69]). Competitive employment is associated with improvements in quality of life and with increased self-esteem, reduced stress, increased socialization, and reduced stigma. When seeing themselves as self-directed agents contributing purposefully to their own patient-centered work goals, patients can make progress toward independence and self-sufficiency in a variety of ways as they are able to see themselves working toward recovery.

Recovery Phase

Recovery does not mean “cure”; rather, patients in this phase are empowered to live meaningful and satisfying lives, having reached many of the overall goals that bring them into normal community settings and

Telegram: @medical_k

www.konkur.in

interactions. In this phase, individuals are more autonomous and self-directed in their choice of person-centered goals and taking steps and garnering resources to continue achieving their goals. They are equal partners with their professional providers of services, making shared decisions and serving increasingly as their own case managers. They often assume paying jobs as peer counselors and peer advocates, in addition to joining with mental health professionals as active proponents of public education and political action for decreasing stigma and improving funding for mental health services in their states and communities.

Stigma toward mental health may lead to social withdrawal and the perception of being devalued or discriminated against, which in turn can affect the self-esteem of patients and become a barrier to recovery. Individuals can also develop a sense of embarrassment and shame. Many social factors may mediate the presence of stigmatization toward patients in recovery, including but not limited to: negative beliefs of family members or support systems toward mental illness itself, social media influence and stereotypes related to mental health, negative attitudes of society in general, attitudes of a healthcare professional during crisis or emergencies, as well as structural discrimination experienced by the individual. There is limited evidence about the effectiveness of specific interventions to reduce stigma related to mental health. However, psychoeducation, contact with the mentally ill, stigma self-management, protest, and social activism, as well as legislative reform and advocacy, have been mentioned as potential interventions. Reducing stigma is crucial to decrease barriers during the recovery phase.

Recovered patients are capable of managing routines, work, school, independent living, and illness self-management without direct supervision by relatives or mental health professionals. That being said, it is strongly recommended that recovered persons sustain their connection to mental health services, even if this consists of only occasional “check-ins” with their treatment providers, given the increased vulnerability to relapse and stress sensitivity often experienced by individuals who have experienced serious mental health disorders. Refresher courses for patients’ emergency plans to implement relapse prevention are one mechanism to extend recovery for longer periods of time.

ASSESSMENT IN PSYCHIATRIC REHABILITATION

Telegram: @medical_k

www.konkur.in

The assessment of persons with SMI involves a thorough and holistic assessment of a number of important domains with specific well-validated tools. The goal of any good assessment is to render an accurate diagnosis and then to suggest areas that can be targeted with specific interventions. The key to a comprehensive assessment of SMI is a thorough clinical assessment of the presence of symptoms, including the nature, frequency, intensity, and duration of particular symptoms. It should be noted that the management of certain symptom clusters (e.g., reduction of hallucinations and/or delusions) but not others (e.g., apathy, social cognition, and interpersonal skills) may not be specifically addressed by specific pharmacologic and behaviorally-based treatments. In addition, reduction of symptoms is not analogous to a “cure” for most individuals since neurocognitive and behavioral deficits in conditions such as schizophrenia may persist after symptomatic relief of positive symptoms. A number of symptom rating scales include the PANSS, the BPRS, and the Scale for the Assessment of Negative Symptoms (SANS). These instruments can provide useful and important information on symptom dimensions and provide a common basis by which to come to inform clinical and research diagnosis as well as to assess outcomes. This appraisal is vital as an initial step in creating a collaborative recovery plan.

As with many assessment instruments, interpretation of these measures depends on the operationalization and validity of specific symptom constructs as well as their ability to designate which cluster of symptoms meets the criteria for a particular psychiatric condition. It is important to take into account the fact that many psychiatric syndromes have overlapping features and differences in symptom presentation can be a function of the stage of illness, time of onset of a psychiatric episode, and the context and environment in which the patient is assessed. Many persons with SMI have comorbid psychiatric and medical disorders such as co-occurrence of SUD. Further specific endocrine, metabolic, and neurologic disorders may produce symptoms that mimic psychiatric symptomatology. In addition, an assessment of coping skills, daily living skills, housing arrangements, level of education and employment, family involvement, and social, sexual, and spiritual needs should be integrated into the holistic assessment of SMI.

One of the big challenges in the field is that controlled clinical trials often use relatively stringent inclusion and exclusion criteria that do not

Telegram: @medical_k

www.konkur.in

account for all of the comorbid psychiatric conditions, medical conditions, polypharmacy, and important mediating factors such as adherence, supported employment services (SES), environmental supports, and cross-cultural issues. As a result, it is increasingly important to ensure that findings obtained from placebo-controlled, randomized clinical trials generalize to individuals in different medical, hospital, and community mental health settings. While controlled randomized clinical trials may possess internal validity, the true test of an intervention is its effectiveness in real-world community settings.

Neurocognitive Symptoms

Cognitive assessment is a crucial component of the assessment of SMI, particularly in schizophrenia, given the number of impairments associated with the disorder and its challenging effects on activities of daily living and functioning. Neurocognitive deficits are thought to be a core feature of schizophrenia and often include emotional processing, perceptual disturbances, attention, sensorimotor integration, executive function, context processing, social perception, processing speed, and working memory. Up to 40% of persons with bipolar disorder may have completely normal cognitive profiles. In contrast, up to 75% of persons with schizophrenia perform below general population standards on neurocognitive tasks. Early identification of neurocognitive deficits in individuals living with schizophrenia is important as these deficits strongly correlate with chronic disability.

A tremendously positive development in schizophrenia research has been the development of the Measurement and Treatment Research to Improve Cognition in Schizophrenia (MATRICS) and Consensus Cognitive Battery (MCCB) for the assessment of schizophrenia. As a gold-standard assessment battery, the MCCB tests for ten cognitive domains take approximately 60 to 70 minutes to administer and allow researchers to standardize trials. The MCCB has not only been successful in research on schizophrenia but has also been able to differentiate Bipolar I and Bipolar II patients from controls. It has been recommended that because of the more subtle nature of cognitive deficits in schizophrenia, additional tests that should be considered (besides the MCCB) include the California Verbal Learning Test-II (CVLT-II). In addition, the Wisconsin Card-Sorting Task, Trails B, and the Stroop Color-Word task are all measures that should be considered. Moreover, a shorter (10-minutes) easily-

Telegram: @medical_k

www.konkur.in

administered battery, the Brief Cognitive Assessment Tool for Schizophrenia (B-CATS), has been developed to assist clinicians in the cognitive assessment of individuals living with schizophrenia, with proven good test-retest reliability and correlating 0.76 ($P < .01$) with the MATRICS battery.

An interview-based assessment of cognition specifically for schizophrenia is the Schizophrenia Cognition Rating Scale (SCoRS). The SCoRS assesses cognitive functioning based on interviews with both patients and their caregivers. The assessor then incorporates both sources of information to determine a final rating. Performance on the SCoRS has been found to be associated with both actual performance on cognitive tests and measures of real-world functioning. One study indicated that patients with schizophrenia who perform “normal” on cognitive testing do not indicate an association between cognitive performance and social or vocational functioning.

The challenge with any neuropsychological assessment is that there are confounding factors in SMI other than underlying putative brain damage that may contribute to poor performance. For example, poor motivation, sedation and other cognitive effects of medications, social anxiety, paranoia or hypervigilance, and interactions with the test examiner may have significant effects on test outcomes. In some settings, attention and motivation to perform may be so low that the neuropsychological battery with the Tests of Malingering and Memory (TOMM) or Green’s Word Memory Test (WMT) is augmented. It is important that any neuropsychological assessment that is performed is not in the acute stages of SMI. It is much more helpful to conduct neurocognitive evaluation after ample stabilization has occurred. There is a tendency to think that neuropsychological testing taps orthogonal, independent cognitive domains but deficits in memory and measures of verbal fluency may all be related to generalized cognitive slowing, attentional deficits, and reduced speed of processing. While there have been attempts such as the National Institute of Mental Health (NIMH) initiative (Cognitive Neuroscience Treatment Research to Improve Cognition in Schizophrenia [CNTRICS]) aimed to develop measures derived from cognitive neuroscience, with explicit links to known neural systems and psychopharmacology, the field is still hampered by a locationist notion of the brain where a function is thought to occur in specific brain regions (e.g., amygdala) rather than distributed networks of

Telegram: @medical_k

www.konkur.in

neuronal activity that involve multiple brain regions. This highlights the importance of relating neurocognitive function to functional measures such as fMRI and PET in order to identify working neural networks in the brain.

Social Cognition

Social cognition involves a variety of socially relevant domains, including emotion perception, social problem-solving, understanding social cues, and interpretation of others' attitudes and intentions. There is increasing evidence that negative symptoms of schizophrenia have an impact on both social competence and social outcomes but do not exert an influence on social cognition. However, social competence and social cognition have significant effects on real-world social outcomes. The result of the Expert Panel and Rand Survey identified four major domains of social cognition that include (a) emotional processing, (b) attributional style/bias, (c) social perception, and (d) theory of mind (ToM)/mental state attribution. Measures that the committee agreed upon for final inclusion in the battery to assess the aforementioned domains included the abbreviated version of the Ambiguous Intentions and Hostility Questionnaire (AIHQ), Bell Lysaker Emotion Recognition Task (BLERT), Penn Emotion Recognition Test (ER-40), Hinting Test, abbreviated version of Relationship Across Domains (RADs), Reading the Mind in the Eyes Test, The Awareness of Social Inferences Test (TASIT), and the abbreviated version of the Trustworthiness Test.

As part of the Social Cognition Psychometric Evaluation (SCOPE) study, the results of the final validation study showed that the BLERT, a test of affect recognition, the ER-40, and the Hinting Task (ToM) had the highest psychometric properties among a number of social cognition tasks and are the ones recommended for use in clinical trials. Meanwhile, the TASIT, Intentionality Bias Task (IBT), and Eyes Test showed weaker psychometric properties and remain in need of further study. On the other hand, the Mini Profile of Nonverbal Sensitivity (MiniPONS) and the Social Attribution Task-Multiple Choice (SAT-MC) showed poorer psychometric properties, and caution should be exerted when considered for clinical trials.

Nowadays, pharmacologic interventions may be used in conjunction with social cognitive training to facilitate the improvement of neurocognitive symptoms. Aerobic exercise has been found to have

Telegram: @medical_k

www.konkur.in

positive social cognitive effects and may be useful when introduced in conjunction with social cognitive interventions.

Communication and Social Skills

Deficits in metacognition, the ability to construct complex ideas about oneself and others, and the ability to respond to social and psychological challenges underlie many of the communication and social skills deficits found in schizophrenia. This mismatch between perceptions of oneself and the world and communication with others in the environment can cause considerable difficulties for an individual with schizophrenia. Impaired communication and language skills have been identified as common in schizophrenia, and it has been shown that individuals with schizophrenia have greater social skills deficits than those diagnosed with major depression or bipolar disorder. Those with schizophrenia appear to have social skills deficits that are intermediate.

SST is based on behavioral principles of modeling; shaping, rehearsal, and positive reinforcement are all important parts of successful training paradigms. SST aims to develop or improve social interactions, social performance, or interpersonal skills. It should be noted that SST has advocated for helping an individual interact with his/her world. Both social cognition and negative symptoms in schizophrenia carry the most variance in explaining real-world social outcomes. SST has a positive impact on improving the negative symptoms of schizophrenia. This suggests that targeting both social cognition and negative symptoms may be as important as teaching social skills to individuals. The problem with both social skills and expressive and receptive communication deficits in schizophrenia is that there is a complex interaction between social perceptions, integration of thinking about self and others, and behavioral outputs that can all serve to produce negative outcomes affecting social, vocational, and community life. It is likely that the most effective approaches are going to have to focus on the complex interplay between individual perceptual and social cognition deficits, how these interact with more complex metacognitive processes and help modify behavioral repertoires that will foster optimal real-world functioning.

Assessing Functional Outcomes

Broadly speaking, the goal of any psychiatric rehabilitation or remediation effort is to enhance and support optimal functioning in the environment.

Telegram: @medical_k

www.konkur.in

Reaching milestones such as stable romantic relationships or full-time employment are not sensitive measures of functioning. Despite the considerable overlap, there are varying types of functions, including interpersonal communication, the ability to manage one's household affairs, managing one's finances, community affairs, and working in a vocational setting. For example, managing one's household affairs may involve arranging for transportation to the bank or supermarket and understanding bus, train, or subway routes. There are important decisions to be made on how to prioritize income, making sure that income is used for food, housing, and medication before it is allotted for other purposes. Persons must interact and effectively communicate with others and meet daily responsibilities in the community and the workplace. Understanding the individual's psychiatric condition, treatment regimen, adherence to treatment, natural social supports, contextual cues in the environment, and an understanding of a patient's strengths and limitations is critical to helping the individual achieve optimal functioning within the community. This requires assessment techniques that allow for appropriate targeted interventions and remediation strategies. Proper assessment allows for optimal treatment and psychiatric rehabilitation. These are not two distinct entities but rather a continuous effort to promote wellness and maintain optimal function in many contexts.

A critical distinction between functional capacity and functional performance is crucial. Functional capacity refers to the ability and the underlying nonsocial skills required to successfully perform activities of daily living in the community. Functional capacity can encompass a wide range of activities such as (a) the ability to count money or balance a checkbook, (b) having sufficient social cognition to understand implicit rules regarding social interactions or behaviors, (c) adequate social skills to successfully navigate a work or community environment, (d) requisite cognitive abilities such as intellect, memory, reasoning, language abilities to engage in meaningful home, community or occupational activities. Examples of functional capacity include balancing a checkbook, preparing a meal, understanding, completing work tasks adequately (i.e., taking medications as prescribed), and using the public transit system. If a person does not possess adequate functional capacity (requisite skills required for independent or even assisted living), then the focus of psychiatric rehabilitation has to be on attempting to build and foster those skills that will result in the greatest independence and quality of life. On

Telegram: @medical_k

www.konkur.in

the other hand, functional performance, while often dependent on underlying functional capacity, refers to the actual ability to consistently perform a variety of skills in a way that maximizes autonomy, quality of life, and the ability to cope with real-world demands. The functional performance then represents the actual performance of the individual in the interpersonal, social, financial community, and vocational domains.

Individuals with a psychiatric condition such as bipolar disorder may have an excellent underlying financial capacity, intellectual skills, social cognition, and awareness and be able to live independently and be gainfully employed. However, because of the episodic recurrence of a wide variety of mood symptoms, there may be certain periods where they may fail to adequately manage their manic, depressive, or mixed episodes and may mismanage finances, have difficulties meeting the demands of home, work, or family and be incapacitated despite their high premorbid levels of functioning. Individuals living with schizophrenia may have intact financial and adequate cognitive skills to manage to work and live independently in some settings. However, persistent difficulties with negative symptoms and social cognition can lead to problems that may negatively affect their ability to support themselves and their families. Primary and comorbid substance abuse can radically cause a patient to make poor choices and to allocate financial resources to their addiction or dependency, thus threatening their living situation. Psychiatrists are confronted with the unfortunate challenge that many unsheltered, socially impoverished, and disadvantaged individuals have underlying psychiatric conditions and lack proper support systems that could substantially help to improve their well-being and quality of life.

The distinction between functional capacity and general real-world functional performance is critical in that these constructs dictate the approaches that one will take toward assessment and subsequent management. Skill-building and other approaches are necessary to help increase functional capacity (i.e., via individual or small groups SST). However, the effectiveness of these approaches can only be seen when they form the building blocks to enhance functional performance (i.e., generalizing SST to real-world community and/or occupational settings). Thus, assessment of functional capacity and real-world performance are critical elements in psychiatric rehabilitation. Functional capacity and performance can further be subcategorized with regard to particular domains such as cognitive, financial skills and judgment, social cognition,

Telegram: @medical_k

www.konkur.in

social skills, and judgment that affect individual autonomy and quality of life. Further, specific types of functional skills required for everyday living may pertain to specific domains such as caring for one's self in the home, successfully interacting with the community, or learning and maintaining job-specific skills. This suggests that functional assessment strategies need to be tailor-made for each individual and display reliability (consistency of measurement) and validity (assessing the construct that needs to be measured).

Types of Functional Assessment. Functional assessment can be employed in a number of ways. The most direct method of assessing functional capacity is direct observation of the patient performing behaviors in the clinical setting. One widely used "paper and pencil" measure, such as the Performance-Based Skills Assessment (UPSA) developed by investigators at the University of California, directly assesses the individual's functional capacity with regard to finances, communication skills, household chores, transportation, and planning recreational and other activities. The advantage of such a measure is that it is easy to administer, has demonstrated reliability and validity, and can provide direct and quantifiable information on functional capacity.

Knowledge of deficits in functional capacity can be critical for initial assessment as well as response to treatment. However, a performance-based assessment may not always map onto the individual's performance in the community. In this case, a qualified informant such as a friend, family member, or healthcare provider can provide essential information based on repeated observations of the individual in the context of different environmental supports and contextual cues. Specifically, a reliable collateral informant can provide essential information that may simply not be available by performance-based functional assessment. However, the quality of the informant matters and an assessment of the frequency and nature of the relationship may be beneficial. If a collateral informant has little opportunity to observe the patient, has a cognitive, psychiatric disability themselves, or self-serving biases, their report may be of little value in providing useful functional information. While it is always important to obtain and respect the individual's evaluation of their real-world functional performance, it is important to note that in schizophrenia and other neuropsychiatric conditions such as Alzheimer disease (AD) and other neurodegenerative disorders, reports are often positively biased

Telegram: @medical_k

www.konkur.in

(i.e., the patient often reports a much higher level of functional performance than may actually be the case). Anosognosia, or the “inability to appreciate what one does not know,” is a neuropsychological condition that is seen in traumatic brain injury (particularly within the right hemisphere), AD, and psychotic disorders such as schizophrenia. A 2020 study showed that overconfidence in a social cognitive emotion recognition task in participants with schizophrenia was a predictor of poorer performance on every performance-based task, including other social cognitive tests and measures of neurocognition.

As a result, it is often very useful for the clinician to compare the report of the patient and reliable informant and to also use performance-based functional assessment tools and rating scales. In addition, computer-based performance assessments have emerged, such as the Virtual Reality Functional Capacity Assessment Tool (VRFCAT). VRFCAT involves assessing function in a simulated virtual world, including tasks such as: preparing a shopping list, riding a bus, shopping in a store, and managing money. One study has shown that it is feasible to use technology-based functional capacity assessment protocols with older adults and patients with schizophrenia by conducting the assessment on a touch screen computer, with a battery of tests including ATM banking/financial management, prescriptions refill via telephone/voice menu system, and forms completion (simulating a clinic and patient history form). However, it is important to note that an individual’s ability to complete these skills in a simulated and controlled environment differs from completing these skills in day-to-day life. An individual with prominent negative symptoms of schizophrenia may struggle with avolition and anhedonia and thus would have a lack of motivation for completing such tasks in the real world. Defeatist attitudes in individuals with schizophrenia have been shown to affect variance in negative symptoms, as well as neurocognition and functional outcomes. It is important to assess the individual’s motivation in engaging in these rehabilitative assessments and interventions.

Functional Assessment Scales. In addition to the UPSA, the performance-based measure of functional capacity, a study also notes important scales for functional capacity such as the ILS and Test of Adaptive Behaviors (TABS). Everyday functional rating scales selected by the RAND expert panel include the Independent Living Skills-Survey

Telegram: @medical_k

www.konkur.in

(ILSS), Specific Levels of Functioning Scale (SLOF), Life Skills Profile (LSP), Birchwood Social Functioning Scale (SFS), Social Behavior Schedule (SBS), and Heinrichs-Carpenter Quality of Life Scale (QLS).

The most widely employed measure of functional capacity, the UPSA, is a particularly compelling scale of functional capacity that has shown correlations of 0.6 to 0.7 with neurocognition in a number of studies. The USPA requires specialized personnel for administration. It includes simulations of everyday activities of daily living such as communication (i.e., dialing the telephone to schedule a physician appointment, obtaining and dialing a number from a telephone operator); comprehension/planning (reading and planning a recreational outing such as to the beach on a hot sunny day); finance (counting currency, making change, and paying a bill); household management skills (e.g., shopping for grocery items), and transportation (using a bus schedule in planning a trip and understanding charges and obtaining route information). Some versions of the UPSA include a medication management subtest and are referred to as the UPSA-II. USPA-B is a shorter version of this instrument that focuses on communication skills and finances.

The SLOF relies on self or informant reports but is especially useful when employed by a high-contact clinician. The scale taps the following domains: Participation in Community and Household Activities, Interpersonal Relationships, Work Skills, Self-Care, Physical Functioning, and Socially Acceptable Behavior subscales.

The UPSA has the advantage of being an objective performance-based functional measure and is preferable to self-reports of patients who often overestimate their abilities or questionable informants. Critics of the UPSA maintain that the UPSA measures tap functional behaviors but that they are more psychometrically similar to cognitive measures. There are contextual cues in the real-world environment that dictate real-world functional performance apart from demonstrating capacity in contrived clinical and laboratory settings. Measures such as the SLOF are most effective when used with informants but may in some cases be susceptible to reporter biases. The SLOF and other functional rating scales are typically most effective in the hands of a high-contact clinician who knows the patient well and can weigh informant and patient reports against his/her own clinical judgment. While the SLOF has been extensively validated with schizophrenia patients, studies have shown that 64% of patients with bipolar disorder showed evidence of deficits in one or

Telegram: @medical_k

www.konkur.in

more SLOF domains. The UPSA-1, UPSA-II, or UPSA B has been employed with a large number of patient groups, including those with major depression, bipolar disorder, and schizophrenia. Importantly, the instrument has also been employed in diverse cultural and language groups. A systematic review found that SLOF had the strongest observed correlation with the UPSA.

Other important scales in psychiatric rehabilitation include the Maryland Assessment of Social Competence (MASC), a structured role-play designed to assess social skills. Other scales use time-sampling techniques consisting of numerous observations of patient social behaviors, such as the Time Sample Behavioral Checklist (TSBC), Clinical Frequencies Recording System (CFRS), or Staff-Resident Interaction Chronograph (SRIC) but are usually only appropriate for institutional and residential treatment settings since these involve extensive ratings by staff members.

SPECIFIC APPROACHES

Cognitive Remediation in Community and Occupational Function

Neurocognitive deficits are core features of schizophrenia, and moderate to severe cognitive impairments are present in the vast majority of cases. CR may lead to small to moderate improvements in negative symptoms and social functioning, in addition to cognition. CR can be especially beneficial for persons experiencing subjective cognitive symptoms with schizophrenia and for individuals experiencing vocational challenges. This approach generally starts with simple information processing tasks, and then progresses toward more complex tasks such as targeting working memory and planning.

Cognitive remediation therapy (CRT) is an intervention that enhances cognitive performance in individuals with schizophrenia. However, other psychosocial interventions may be needed to improve functional outcomes. In the last two decades, studies have focused on identifying psychological and nonpsychological approaches to enhance social cognitive interventions and improve functioning. Even early in the course of psychotic disorders, social cognitive interventions can be helpful, and evidence shows that social cognitive deficits are present during the prodromal phase of individuals at high risk of developing psychotic

Telegram: @medical_k

www.konkur.in

disorders. As not all individuals benefit from social cognitive training, combining this approach with psychopharmacology may be promising.

The most commonly used measures are memory scales such as the Rey Auditory Verbal Learning Test (RAVLT) or CVLT-II. Executive function is often measured by the Wisconsin Card Sorting Test (WCST) or Trails B (although this measure taps many aspects of neurocognitive function) or measures of the Delis-Kaplan Executive Function System (DKEFS). Digit symbol of the WAIS-IV is a good measure of processing speed, as is Trails A. Examples of widely used neurocognitive batteries include the MATRICS MCCB, the Brief Assessment of Cognition in Schizophrenia (BACS), and Repeatable Battery for the Neuropsychological Assessment of Schizophrenia (RBANS).

When combining CR with functional skills training, better results in community living skills occurred than with functional training alone. An important review indicated that poor neurocognitive function had significant effects on vocational and occupational status within the community setting. Subsequent investigations revealed that CR plus SES enhanced positive employment outcomes, whereas other studies have not shown such effects. The notion is that training component cognitive abilities in the hopes that they will generalize to specific real-world behaviors may be less important than directly training target behaviors of interest. As an example, consider an adult with schizoaffective disorder who is working in a supported occupational setting. One approach might be to train specific cognitive component abilities in the hopes that they will generalize to the work setting. An alternative approach would be training those skills required for job-related performance. For example, CR strategies would specifically target actual job-related activities such as organization, strengthening procedural memory for certain role activities, and employing strategies to monitor performance. This targeted functional training would involve the cognitive aspects of the skills related to employment but directly integrate this training in an integrated manner and in a manner that would more likely generalize to the employment setting. Some studies have indicated that CR can be associated with neuroadaptation, though it is unclear if there are other factors influencing these results and if results persist with time.

Rehabilitation of Social Cognition

Telegram: @medical_k

www.konkur.in

There has been an increased interest in moving beyond merely framing core features of schizophrenia in terms of positive and negative symptoms and neurocognitive impairment. There has been emerging evidence that deficits in social cognition can also be considered core and stable features of schizophrenia. Social cognition pertains to the perceptions, beliefs, and interpretation of other people's behaviors. Poor social cognition can significantly impair a person with SMI to appropriately respond to others in their environment. Green and others described five major aspects of social cognition; (1) ToM generally refers to an individual's ability to infer the beliefs and perceptions of others; (2) Social knowledge consists of the understanding of rules and conventions that underlie social behavior and guide social interactions; (3) Social perception is the ability to recognize general rules concerning roles and societal rules; (4) Emotional processing involves the experiencing and use of emotions and has been linked with emotional intelligence; and (5) Attributional bias involves attributing causality to both positive and negative outcomes. Each of these components is critically important in understanding how an individual relates to others in the community and their vocational performance. It should be noted that deficits in social cognition are not only observed in those with schizophrenia but also in individuals with bipolar disorder and, to a lesser extent, those with major depressive disorder.

There is increasing evidence that social cognition accounts for far more variability in community function than neurocognitive abilities. Moreover, a meta-analysis of studies on social cognition revealed that social cognitive training procedures have relatively large effects on emotion recognition, small to medium effects on measures tapping ToM effect, and no effects on attributional bias or social perception. One of the most important findings in this study is that these kinds of techniques have a moderate to large effect on community functioning. However, there may be less of an effect on higher-order social cognitive functions, which may improve more by using virtual reality such as the RC2S (CR of social cognition), which involves navigating a computerized character through situations that require emotional processing and learning contextual cues.

A 2018 meta-analysis of neuroimaging studies examining brain activation during facial emotion recognition and ToM tasks in patients with schizophrenia found neural-related circuit disruptions (i.e., reduced recruitment of the right insula, anterior cingulate and medial prefrontal cortex, and increased activation in the bilateral parietal cortex) leading to

Telegram: @medical_k

www.konkur.in

complex impairments in social cognition. Later on, a 2020 meta-analysis further described neural correlates known to play a role in social cognition of those with schizophrenia (i.e., bilateral anterior insula, right temporoparietal junction, left amygdala, and dorsolateral prefrontal cortex), suggesting that these brain areas should be studied as a potential target for therapeutic interventions in this population. Other small studies examining effects of social cognition intervention found neuroplasticity changes, including a reduction in grey matter loss, increase in regional brain activity, and decrease in alpha-range EEG activity, though these studies require to be replicated.

Cognitive-Behavioral Therapy

CBT is a type of psychotherapy based on principles of conditioning, learning, and cognition. As applied to schizophrenia, CBT engages patients collaboratively, challenging their interpretations of events or experiences. In schizophrenia, CBT aims to reduce the intensity of delusions, hallucinations, and related anxiety, to develop more adaptive behavior, and to encourage engagement of the person in relapse prevention. In many cases, the reduction in anxiety that accompanies modified attributions regarding voices leads to a reduced frequency and intensity of hallucinations. Individuals who are able to reframe or find alternative explanations for their positive symptoms can experience relief from these symptoms. If an individual resists challenging these symptoms, the CBT provider can encourage the individual to identify coping mechanisms to reduce distress related to these symptoms. In the case of negative symptoms of schizophrenia, CBT is often used to challenge anhedonic beliefs, schedule activities, and administer self-rewards for increasingly engaging in pleasurable activities. CBT can be provided in individual or group settings and works best with patients who are willing to actively participate in treatment, often as the result of distress from symptoms and/or at least minimal insight into the abnormal nature of their experiences.

A 2014 meta-analysis of 14 studies including 1,484 patients found that compared to other adjunctive measures, CBT showed a significant reduction in positive symptoms. The specific symptoms alleviated with adjunctive CBT include delusions, distress, or delusions related to auditory hallucinations, paranoia, and negative symptoms. Improvements in distress related to auditory hallucinations and delusions were

Telegram: @medical_k

www.konkur.in

maintained at follow-up. A more recent meta-analysis of CBT for schizophrenia conducted in 2018, including 33 studies with a total of 1142 participants with schizophrenia and positive symptoms, measured response rates to CBT by the degree of improvement. In this meta-analysis, 44.5% of patients exhibited a 20% (minimally improved), and 13.2% of patients exhibited a 50% (much improved) reduction of overall symptoms. However, the degrees of improvement reported on positive symptoms showed 52.9% (minimally improved) and 24.8% (much improved) in patients.

It seems that CBT may help patients presenting with psychosis. However, the effects may be small to moderate. Further research is needed to assess the efficacy of CBT for schizophrenia on social functioning, quality of life, relapse prevention of psychotic episodes, insight, and other outcomes. Meanwhile, it is worth noting that in addition to problems uniquely associated with psychotic disorders, various forms of CBT are effective for addressing generalized anxiety, panic, social anxiety, depression, obsessive-compulsive symptoms, and SUD. These problems may co-occur with chronic psychotic disorders, and there is no reason to believe that CBT interventions are any less effective in treating them in people with schizophrenia than in the general population.

Most patients with schizophrenia are able to engage in CBT despite exhibiting acute psychosis and cognitive deficits, as long as they are somewhat motivated to engage in CBT. Motivated patients typically demonstrate good treatment responses, whereas unmotivated patients often do not respond or drop out of treatment. A major challenge is to find ways to engage patients exhibiting first-episode psychosis in CBT. Often, more supportive efforts are needed to engage first-episode patients in the treatment system prior to initiating CBT.

Social Learning and Social Skills Training

The social learning program (SLP) is a comprehensive, integrated set of learning-based techniques (typically including a token economy) and skills-training activities. In most cases, an SLP is delivered within the context of a residential facility, usually for patients with severe and chronic behavioral disabilities. A key feature of the SLP is that all staff members on all shifts are trained to structure their interactions with patients in specific ways during all waking hours. Research indicates that SLP is the most effective form of inpatient treatment for people with schizophrenia,

Telegram: @medical_k

www.konkur.in

including the so-called “treatment-refractory” patients. The SLP has demonstrated effectiveness with a wide range of people with disabilities in a variety of settings (e.g., state and private hospitals and maximum security forensic hospitals). The components of the SLP form an extremely positive teaching environment that assists clients in developing adaptive behaviors and skills relevant to successful return to the community. Contemporary versions of this approach incorporate skills-training technologies, psychiatric rehabilitation techniques for engaging clients, CBT, vocational rehabilitation, cognitive rehabilitation, and substance abuse treatment.

A guiding assumption of the SLP is that all persons with severe mental disorders, no matter how severe the impairments, can learn new behaviors and skills and, therefore, progress to less structured environments. To promote behavior change and skill acquisition, the SLP incorporates a wide variety of techniques based on fundamental learning principles. Differential reinforcement forms the basis of many of the procedures of the SLP. Staff at all levels and disciplines are highly trained and carefully supervised in the timely and consistent delivery of verbal praise, positive social attention, and material reinforcement for adaptive behaviors and the application of extinction or response-cost techniques for bizarre, aggressive, or rule-violating behaviors. Effective SLPs deliver much more positive reinforcement than extinction or response costs. The result is a highly reinforcing, positive, and supportive environment.

Although most comprehensive SLPs include some sort of token economy or point system to deliver feedback and behavior-related consequences, some use individual behavioral contracts, contingency management plans, or social reinforcement alone. However, in all well-designed SLPs, specific objectives and goals of clients are individualized, as are the specific interventions for assisting them with acquiring the skills necessary to accomplish these goals/objectives. Another key feature of all effective SLPs is that, as patients begin to demonstrate improvements in behaviors, there is a planned and systematic withdrawal of tokens or points and an emphasis on generalization training so that clients will be able to apply acquired skills and knowledge successfully in “real-life” community settings under more natural, primarily social reinforcement conditions.

An effective SLP is based on a wealth of data that is generated during all waking hours by all staff, using a number of observational rating

Telegram: @medical_k

www.konkur.in

procedures (described in the section on assessment). The availability of data on all critical behaviors (e.g., grooming, attendance at groups and activities, social contacts, and aggressive behavior) allows for sophisticated data-driven treatment planning. Moreover, the ability to demonstrate specifically to patients why their privileges or other consequences of their behavior are occurring and what needs to change, and how much to receive different consequences is a powerful tool. In effect, this type of data-driven system serves to instill responsibility for behavior change in the patient, instills a sense of agency and mastery regarding behavior change, and reduces the institutionalized and dependent attitude that staff arbitrarily determine privileges, which is so often found in state hospital settings. Moreover, as demonstrated in a recent study, patient satisfaction with treatment is often high in SLPs.

Given the complexity, specificity, and range of procedures involved in the SLP, staff training is of paramount importance. All staff members are involved in extensive initial and ongoing training, using both didactic instruction and in vivo practice. Competency-based supervision is provided through regular performance feedback, using observational data on staff-patient interactions and structured supervisory observations.

Another important feature of SLPs is the focus on the generalization and maintenance of gains after program discharge. As patients acquire skills and develop goals for community living, they are provided with opportunities to apply these skills and pursue their goals in community settings. After discharge, declining contact aftercare is provided. Some SLPs arrange to train staff at community residential facilities to maximize the maintenance of gains after discharge.

SLPs have traditionally been provided in long-term treatment units. Recently, however, modifications of the full program have been tried in other settings, such as acute inpatient units and community-based residential settings for outpatients with SMI, with demonstrated success.

Illness/Wellness Management Skill Training

Gaining the ability to manage one's psychiatric illness is central to the rehabilitation and recovery perspective. In the rehabilitation and recovery literature, skill training in illness/wellness management has gradually been differentiated from related social, and living skills approaches, reflecting a growing recognition that specialized skills are needed to self-manage psychiatric disorders, comparable to skills needed to self-manage physical

Telegram: @medical_k

www.konkur.in

conditions such as diabetes. When providing persons with SMI the knowledge and skills, they are empowered to manage their own symptoms, make informed decisions about their treatment plans, and identify their recovery plan. People learn about the episodic and persistent symptoms of their illness, the relationship between symptoms and functional impairments, pharmacologic options and other behavioral techniques (e.g., relaxation and stress management) for controlling symptoms, medications side effects, identification of “warning signs” of an impending relapse, creating a relapse prevention plan, skills to collaboratively communicate with the rehabilitation team, mental health providers and family who can support their recovery journey, and various other aspects of their disorder and its management. Behavioral skills indirectly relevant to disorder management include, for example, the assertive skills necessary for dealing with the doctor and the doctor’s receptionist in getting an appointment for a medication visit. Integrated Illness Management and Recovery (I-IMR) programs target patients who have psychiatric disorders and comorbid medical conditions. Wellness self-management includes directing individuals with issues relating to lifestyle choices, nutrition, physical activities, relationships, spiritual and pleasurable activities.

Several developer groups have packaged illness/wellness management skill training materials for testing and dissemination. A number of original studies and reviews confirm the effectiveness of skill training focused on illness/wellness management for improving adherence to treatment in people who live with SMI. The SAMHSA has produced packages for public dissemination that fall under this category, including What Individuals in Recovery Need to Know About Wellness, Illness Management, and Recovery, and Medication Management Approaches in Psychiatry. Both packages include materials for all participants in the illness/wellness management process, including the person in recovery, physician, other service providers, family, and friends. The Agency of Healthcare Resource and Quality (AHRQ) created a Self-Management Support Resource Library with training material for providers as well as patient material on self-management. These resources can be accessed on AHRQ’s website: https://www.ahrq.gov/ncepcr/tools/self-mgmt/home.html

Illness/wellness management training for people with schizophrenia benefits from relapse prevention and related techniques. Relapse

Telegram: @medical_k

www.konkur.in

prevention programs work with individuals to identify environmental stressors that can trigger warning signs of relapse, develop steps that can be taken to prevent relapse, and teach individuals stress management techniques. Well known for its application in substance abuse, many of the techniques of relapse prevention are well suited to the episodic nature of the lived experience of people living with schizophrenia, the role of stress in precipitating psychotic symptoms, and the important role of the recovering person in managing those episodes. The original application of relapse prevention is also of interest and should be further studied, given that people with schizophrenia often have substance abuse problems as well. Peer involvement is also especially relevant to illness/wellness management.

Supported Education

Supported education prepares people with psychiatric disabilities to achieve educational goals in an academic setting in a person-centered approach, including starting college or continuing interrupted college education due to mental health issues. A retrospective study examining medical records of 114 patients with the first episode of psychosis (FEP) found that 82% of individuals enrolled in college experienced interruptions in their education following FEP. Supported education can help forge a path for individuals with SMI to develop future careers or engage in meaningful work. A randomized controlled trial in 2017 found that a comprehensive, team-based treatment program that includes supported employment and education for individuals following FEP was associated with greater improvement in work or school participation.

Supported education addresses ways to overcome obstacles related to achieving educational success, such as improving academic skills and problem-solving, bolstering self-confidence, and engaging in career development. Every college has its own policies regarding disability support services, with accommodations varying depending on the individual's needs. Registering with the college's disability resource office, providing documentation of the diagnosis, prior and requested academic accommodations, and collaborating with the college disability resource center are some of the steps needed to be taken by individuals with SMI to obtain supported education.

Many models of supported education exist, including contained classrooms, onsite support, and mobile support. In the mobile support

Telegram: @medical_k

www.konkur.in

approach, a counselor meets one-on-one with a student to tailor an individualized plan to maximize academic success. This may include assistance in accessing services already in place in the educational setting, help with locating and using school social and recreational services, preparatory coursework, case management support, ongoing support and check-in meetings at the local student center, study support, visits to the campus library, linkage support to other campus services, and individual counseling (didactic, supportive, and/or exploratory). Other models of supported education include didactic group meetings in a classroom setting focusing on study skills, supportive group meetings, and the provision of standard study guides. Evidence from these programs suggests that distress levels are higher in people with schizophrenia than in other students. This should lead to further efforts to introduce stress management techniques into supported education activities for patients with schizophrenia. In addition, some rehabilitation programs offer wellness and resilience training, as well as academic coaching for individuals with SMI who are on college leave.

Sex Education

Many individuals with SMI aspire to and achieve meaningful education, work, and enjoy mutually supportive family and intimate relationships. The topic of intimacy and sexuality has been given the least attention in this population by mental health professionals. Surveys have discovered that 60% to 70% of adults with SMI report being sexually active in the last year, with approximately 30% reporting two or more partners. Persons with SMI are more likely to be involved in risky sexual behaviors, including inconsistent condom use, multiple sexual partners, and transactional sexual acts. In addition, some psychotropic medications are associated with sexual side effects. Persons with chronic mental illness are also more likely to experience intimate partner violence as well as sexual exploitation.

Sexuality and sexual expression should be recognized in all individuals living with chronic mental illness. The World Professional Association for Transgender Health (WPATH) has created a standard of care guideline for health professionals caring for transgender and gender diverse, including guidelines on psychological well-being, social support, and individual fulfillment. Sexual health education needs to be tailored for lesbian, gay,

Telegram: @medical_k

www.konkur.in

bisexual, transgender, queer, intersex (LGBTQI) individuals. Peer-to-peer support can be beneficial in sexual education.

Clearly, sex education should be an integral part of a comprehensive rehabilitation program. The current impetus for increasing patients' sexual knowledge derives in part from the alarmingly high rates of HIV infection and AIDS found among individuals with SMI. Not surprisingly, the majority of sex education programs have been designed to increase patients' awareness of the risk of infection, dispel misinformation and stereotypes, and provide the knowledge and skills needed to decrease their chances of becoming infected. A meta-analysis examining prevalence data of blood-borne infections in people with SMI found that people with SMI are at risk of blood-borne viral infections, but due to methodologic limits, these prevalence rates may be overestimated. Other contributing factors include low socioeconomic status, substance use, and sex. Emphasizing teaching techniques that use procedural learning and memory can mitigate any cognitive disabilities that may impact learning. In psychiatric rehabilitation, implicit or procedural learning is enhanced by video, and live demonstrations termed social modeling. Other techniques that build on procedural learning and memory are role-playing, interacting with a computer as in computer games, using pictures and attractive graphics to amplify written information, and engaging in repeated practice.

These educational methods can also be used for sex education programs that have broader goals than simply teaching persons with serious and persistent mental illness how to reduce their chances of becoming infected by HIV. Some of the educational objectives that comprise more ambitious and enlightened efforts in this realm include the following:

- Increasing patients' knowledge and comfort about sexuality
- Encouraging patients to identify and clarify their values and attitudes about sexuality
- Informing patients about alternative methods of birth control
- Teaching patients decision-making skills regarding sexual activity
- Overcoming medication-related sexual dysfunction and preventing deterioration or cessation of sexual activity
- Improving intimacy skills
- Imparting basic education on sexually transmitted diseases
- Instructing patients in proper condom use

COMORBID SUBSTANCE USE DISORDERS

The field of psychiatric rehabilitation is confronted with the need to identify and treat SUD as epidemiologic data show high prevalence rates among individuals with concurrent SMI. SUD have been associated with medication nonadherence, underachievement, decreased work productivity, poor health, neuropsychological impairment, social dysfunction, and violence, among other negative biopsychosocial effects. Prospective studies have shown that treatment outcomes, hospitalization rates, housing stability, and functional status are worse among patients with dual disorders. Studies have also shown that problems related to substance use tend to persist over the long term among patients with SMI. Lifetime treatment or help-seeking behavior is uncommon, particularly among those with psychiatric comorbidity. Thus clinicians are encouraged to be proactive with assessing for SUD to mitigate the negative impact on successful recovery and community adjustment.

Historically, individuals with SMI such as schizophrenia and co-occurring SUD received treatment for one disorder but were excluded from the other. Eventually, distinct and parallel treatment programs emerged; however, treatment outcomes were poor using this model. As a result, integrated treatment models combine substance abuse and mental health interventions in one clinical program. This model provides comprehensive outpatient dual disorders interventions as well as integrated residential treatment programs. In integrated treatments for patients with dual disorders, mental health treatments, and substance abuse treatments are brought together by the same clinician, or team of providers, in the same program to ensure that the patient receives a consistent, specific, and holistic explanation of illness and a coherent prescription for treatment rather than a contradictory set of messages from different providers. Integrated treatment aims to improve collaboration between treatment providers, eliminate the patient's burden of attending two separate programs, and remove financial and other barriers to access and retention. Comprehensive programs have frequently included not only standard mental health interventions, such as medication monitoring and support services, but also assertive outreach to engage patients in treatment; intensive case management; trauma interventions; housing supports; and individual, group, and family substance abuse counseling.

Telegram: @medical_k

www.konkur.in

Motivational interviewing, as well as CBT, are often utilized in patients with comorbid substance use and chronic mental illness. Harm reduction such as needle exchange services and pharmacologic therapy such as opioid replacement therapy can be incorporated as well on an individualized basis. Relapse prevention, which is often included in these approaches, focuses on preventing exacerbations of both mental illness as well as substance use relapse. Literature in this area shows that long-term treatment is associated with better overall outcomes. Research efforts are still being made to test and refine individual components and combinations of integrated dual-diagnosis treatments. As with all treatment, effective interventions targeting substance use should be individualized to address personal factors and the stage of motivation.

TOWARD MORE INTEGRATIVE MODELS OF CARE

Current psychiatric rehabilitation extends far beyond previous psychosocial models that were added to medication management and other somatic therapies. Psychiatric rehabilitation today is an active, collaborative, and person-centered endeavor, which necessitates a strong therapeutic relationship, trust, and collaboration between the patient, family, and multidisciplinary treatment team. Excellent treatment is predicated by using state-of-the-art and empirically validated assessments. While neurocognitive deficits may be pervasive in many types of schizophrenia, persons with bipolar or unipolar affective disorder may have less but still significant impairment in this area. In some cases, comorbid substance abuse disorders can further impair already pre-existing cognitive deficits. Equally important is the accurate assessment of functional capacity (based on performance-based tests) and, most importantly, real-world functional performance. Functional performance cannot be limited to merely higher- and lower-order activities of daily living but must also encompass social and vocational functions. There is also increasing evidence that deficits in social cognition and meta-cognition create considerable stress for individuals with schizophrenia beyond typical memory impairments, slow cognitive processing, and other neurocognitive deficits. As previously discussed, there is ample literature to suggest that improving communication skills, enhancing social skills, and behavioral goal attainment are all effective means to help the individual cope with stressors that might increase the likelihood of relapse.

Telegram: @medical_k

www.konkur.in

This chapter has focused on empirically oriented approaches that can help in these efforts. As previously mentioned, it is of essential importance for both the patient and the treatment team to (a) identify targeted short-term and long-term goals that are both operational and obtainable, (b) plan interventions and build supports that are appropriate to a person's stage of recovery, (c) build coping strategies and stress management techniques that will reduce the chances of relapse, and (d) foster a collaborative treatment milieu involving the patient, family, and care providers.

Every person with SMI is a unique individual. While evidence-based approaches can provide guidance in the selection of the best instruments and interventional tools, this can never be done in isolation and without knowledge of the person's strengths, weaknesses, resources, support, and unique personality and environment. The best chances for optimal recovery and stabilization are through a multimodal approach that encourages adherence to medication and targeted treatment goals, stress management, and coping techniques, as well as developing optimal environmental supports.

SMI conditions are like many other chronic medical conditions that need constant attention and management. However, unlike many physical ailments, persons with SMI still have to manage additional stigma and lack of understanding afforded those with chronic medical and neurologic conditions. The most effective interventions will be those with the most empirical support, targeting the many different aspects of deficits in SMI (including but not limited to social isolation, deficits in social cognition, problematic meta-cognition, functional and vocational deficits, as well as problems with communication and social skills). Focusing solely on these targets without recognizing the importance of contextual cues and social supports risks fragmenting care.

Psychiatric rehabilitation is based on providing hope, self-empowerment, resilience, and recovery outlook and works to provide a patient-centered approach for individuals with psychiatric disabilities to accomplish their desired goals. There needs to be continued emphasis on more accessible, inclusive, culturally sensitive, integrated, and comprehensive models of care. Patients deserve no less.

56.7 A Sociocultural Framework for Mental Health and Substance Abuse Service Inequities

MARGARITA ALEGRÍA, PH.D., BERNICE A. PESCOSOLIDO, PH.D., KIARA ALVAREZ, PH.D., AND GLORISA CANINO, PH.D.

The Institute of Medicine defined disparities in health care as "racial or ethnic differences in the quality of healthcare that are not due to access-related factors or clinical needs, preferences, and appropriateness of interventions." Responding to an important gap in the definition, the National Institute on Minority Health and Health Disparities expanded the definition in 2019 to include "a pattern of poorer health outcomes, indicated by the overall rate of disease incidence, prevalence, morbidity, mortality, or survival in the population as compared with the general population" and defined "racial/ethnic minorities, socioeconomically disadvantaged populations, underserved rural populations, and sexual and gender minorities" as those more likely to experience the disparities. Although reports since 2000 have strengthened public concern about glaring discrepancies in patterns of health service use and outcomes for racial and ethnic minorities in the United States, there has been limited progress in disparities reduction from 2000 to 2018.

Most entrenched disparities continue to be associated with the patient's race, ethnicity, and income profile. Ignoring these nonmedical factors represents a lost opportunity to eradicate the augmented age-adjusted mortality and increased burden of disease for minority populations. Despite the attention focused on health services disparities, particularly in view of demographic projections suggesting that ethnic/racial minorities will become the majority of the U.S. population by 2045 and by 2020 for children, we lack strategic approaches that match the complexity of the problem. Understanding the policy, social, and cultural factors that account for and reduce these disparities provides guidance for crafting effective individual interventions and systemic policies. Without

Telegram: @medical_k

www.konkur.in

frameworks and models, implementing the science-to-services translation called for by the National Institutes of Health is challenging.

To date, numerous conceptual frameworks have attempted to chart the potential causes of mental health service disparities. Most are based on the understanding that disparities in mental health and mental health care have no single underlying cause and that mechanisms likely vary across racial/ethnic groups and geographic contexts. Many scholars argue that the *fundamental causes* of health service disparities emerge from macrosocial factors such as historical and contemporary structural racism. Structural racism refers to "the totality of ways in which societies foster racial discrimination through mutually reinforcing inequitable systems (e.g., in housing, education, employment, earnings, benefits, credit, media, health care, and criminal justice, etc.) that in turn reinforce discriminatory beliefs, values, and distribution of resources." Given the entrenchment of structural inequities in resources, policy, and practice, many scholars argue that a targeted focus on structural racism offers a direct and effective approach to finding a solution to health service disparities.

Additionally, some frameworks detail a small set of factors related to a single, particularly important, intermediary mechanism (e.g., residential segregation or employment) of health service disparities. Others seek to provide an overview of a broad range of possible mechanisms. A basic critique of service disparities frameworks is that too many have centered closely on individual-level mechanisms (i.e., supportive social relationships, family networks) and individuals' responses to those circumstances (i.e., optimism, personal agency), which impact psychosocial reserve capacity and cognitive-emotional processes. These models tend to be reductionistic, failing to incorporate dynamic, system-level factors or consider reciprocal effects of different interventions, the context of dynamic reciprocal relations, or issues such as the availability of resources or services in the area. These system forces are vital to grasp the essential issues and to design system interventions. However, targeted factors should be those that matter substantially, are modifiable, and advance the science and public policy practice. Building from past theoretical and empirical work, this chapter updates a culturally informed, complex, population health systems framework for mental health and substance abuse service disparities which integrates a new definition of health care inequities.

Telegram: @medical_k

www.konkur.in

In our effort to integrate sociocultural elements into a health service inequities frame, our definition of health care inequities or disparities refers to *racial and ethnic differences in access, health care quality, or health care outcomes that are not due to clinical needs or the appropriateness of treatment* and that *are a result of systemic, avoidable, and unjust social and economic policies and practices that create barriers to equity in mental health and substance abuse treatment services and outcomes.* Disparities occur across many dimensions, including race/ethnicity, socioeconomic status, age, location, gender, disability status, and sexual orientation. Patient preferences are also included as potential sources of disparities since they do not stem from "undue differential treatment on the basis of race and ethnicity." Past experiences and availability of services patterns might influence racial and ethnic minorities' preferences in treatment. Thus, preferences cannot be disentangled from people's available options in care or from health literacy factors and can contribute to inequities.

This approach to understanding disparities in service delivery emphasizes that sociocultural processes refer not only to race/ethnicity as a particular set of values, norms, and beliefs but also to the historical and concurrent circumstances and experiences leading to a group's social, economic, and political status. In addition, culture creates repertoires or "cultural toolboxes" that provide accepted "go-to" ways to behave, including how to respond to health problems. To understand the relationship between culture and health, a simplistic view of culture or cultural differences cannot work. Cultural processes are fundamental threads connecting communities, health systems, providers, and patients. They "veil" the entire complex system that deals with population health. Nowhere in the Sociocultural Framework (SCF) is the nature and operation of "culture" partitioned in a separate box or, even more importantly, proxied by sociodemographic categories. Racial, ethnic, and national categories are just proxies for markers of culture, pre- and postimmigration histories, and social and economic stratification, and they should be acknowledged as such. Since each individual has a profile of statuses, not just one, that could be subject to discrimination (e.g., member of a minority group, identifies as LGBTQ+, and is an immigrant), understanding and addressing their joint effects on mental health, substance use, treatment, and outcomes is complicated. When researchers are trying to reflect intersectionality (i.e., the convergence of

Telegram: @medical_k

www.konkur.in

multiple devalued statuses) rather than including an ever-expanding set of interacting statuses, Lamont and colleagues suggest focusing on cultural capital and cultural processes that sustain and reproduce societal and health inequities.

THE SOCIOCULTURAL FRAMEWORK: A COMPLEX, POPULATION HEALTH SYSTEMS APPROACH

Many of the recent agenda-setting reports in medicine see many contexts implicated in the cause, treatment, and outcomes of health and disease for individuals, providers, and societies. In many ways, seeing the relevance of everything from genetic risk to national health care policies is not new. From Bronfenbrenner's early ecologic systems theory to the current popularity of socioecologic models, the idea that different contexts matter for human growth, development, and well-being has become the "metaphorical blueprint" for much of basic and translational science. There is a general acceptance that the "environment" or the "environmental context" in its many guises "gets under the skin" and "inside the mind." What is novel here, and often missing in these standard models, is the recognition that much of what happens across these contexts results from the active forces that operate at their borders. Context here is composed of two types: across-level contexts (e.g., place or geography, health care organization, and individuals) and across-system contexts (the community and the health care system). Complex systems theory offers the view that these across-level and across-system interactions tend to persist over time, adapt to changing circumstances, and, as a result, are difficult to alter by addressing only one level or one system. Thinking through how major contexts meet, clash, cooperate or otherwise interact across levels and systems provides novel insights for critical, potential levers of change. Even more importantly, without establishing what happens at the touchpoint of major levels and systems, unintended consequences are likely.

As depicted in Figure 56.7–1, the Socio-Cultural Framework (SCF) for Mental Health and Substance Abuse Service Inequities has three essential elements—systems, levels, and interacting mechanisms. Two key systems in the complex population health system that can produce disparities or buffer inequities are the health care system and the community system. Each operates at three levels—the societal level

Telegram: @medical_k

www.konkur.in

(larger policy or environmental contexts), the organizational level (formal organizations or lay sectors), and the individual level (provider or patient). At each level, these contexts interact or interface to produce the fundamental mechanisms of inequality and bias that cumulate to inequities in health, health care, and quality of life.

Telegram: @medical_k

www.konkur.in

FIGURE 56.7–1. A sociocultural framework for mental health and substance abuse service inequities. (Adapted from Alegria M, Pescosolido BA, Williams S, Canino G. Culture, race/ethnicity and disparities: Fleshing out the socio-cultural framework for health services disparities. In: Pescosolido B, Martin J, McLeod J, Rogers A, eds. *Handbook of the Sociology of Health, Illness, and Healing*. Handbooks of Sociology and Social Research. Springer, New York, NY.)

We follow the Institute of Medicine's (IOM) *Unequal Treatment* Report in focusing on three levels within the health care system:

Telegram: @medical_k

www.konkur.in

1. Federal and economic health care policies and regulations at the state and federal level
2. The operation of the health care system and provider organization
3. Provider/clinician-level factors.

These domains are depicted on the left-hand side of Figure 56.7–1. The SCF extends the IOM framework by adding the parallel focus to the other key system—the community system. These additional levels are drawn from utilization, “take-up” or help-seeking models and include:

1. The environmental level, specifically social and economic forces affecting minority populations
2. The operation of the community networks, including family, friends, and the lay sector
3. Patient-level factors.

These domains are depicted on the right-hand side of Figure 56.7–1.

The touchpoint of the two systems at each contextual level produces six main mechanisms listed in the center portion of Figure 56.7–1. These include:

1. Failure of health care markets, institutional bias, limited financing, and lack of ancillary services leading to decreased access and quality of mental health care and substance abuse treatment services
2. Differential pathways into mental and substance abuse health care leading to differential experiences of treatment, no treatment, or inadequate treatment
3. Poor patient–provider interaction leading to miscommunication, clinical uncertainty, low therapeutic alliance, bias, stereotyping, and clinical errors; and high dropout rates
4. Mismatches in mental health and substance abuse service offerings and minorities’ needs leading to resistance or lack of compliance in health care and under-treatment
5. Lack of community trust and erroneous expectations of services, leading to disengagement and poor collaboration in treatment
6. Limited workforce availability and training of mental health and substance abuse service providers to treat ethnic and racial minorities, leading to reliance on informal or poorly trained providers.

Telegram: @medical_k

www.konkur.in

In sum, at each level, the health care system and community system interact at diverse levels to produce mechanisms that lead to differential health care outcomes in mental health and substance use care, including greater illness severity and diminished quality of life. The levels and systems are linked by and through these mechanisms in a complex population health system. All mechanisms and contexts are set within a shaded region that represents culture. Below, we discuss how the interaction between systems works at each level and operates to impact mental health and substance abuse service inequities. We provide concrete examples of how the six main mechanisms may produce inequities. Because service inequities may also result from interactions between levels, some overlap is inevitable in our descriptions. Where appropriate, we bring in evidence-based concepts and findings not specific to mental health and substance abuse care to identify potential leverage points to reduce inequities that lead to these negative mental health and substance use outcomes or to create testable models tailored for diverse racial and ethnic groups. Finally, we acknowledge that the mechanisms linked to access may differ from those leading to poor quality of care or differential treatment outcomes.

HEALTH CARE SYSTEM DOMAINS

Federal, State, and Economic Policy

Federal, state, and economic policies impacting health and mental health care have the potential to create, exacerbate, or reduce health inequities. Due to their over-representation in government-sponsored programs like Medicaid, populations may face additional challenges as a result of state and federal regulations aimed toward cost control. For example, state differences in implementation of the Patient Protection and Affordable Care Act (ACA), federal financing of Medicaid payments, and the Children's Health Insurance Program (CHIP), all have a disproportionate effect on minority populations. We discuss each, in turn, below.

Affordable Care Act and Medicaid Expansion. A key provision of the ACA is the expansion of Medicaid to include adults with incomes up to 138% of the federal poverty level (FPL, $16,104 for an individual or $27,310 for a family of three in 2014), in order to increase the number of Americans who are insured. A review of 65 studies from 2014 to 2020

Telegram: @medical_k

www.konkur.in

found that states which expanded Medicaid significantly narrowed racial and ethnic disparities in coverage among Latinx and Black individuals compared to White individuals. Few studies examined effects among other racial and ethnic groups, which is an important gap in the research. Medicaid expansion improved disparities in some indicators of access to care, quality of care, and health outcomes (e.g., infant and maternal health). Substance abuse treatment increased, with 36% more people receiving treatment after 4 years of the expansions in expansion states, compared to nonexpansion states. Despite ACA provisions, individual states are allowed to decline the Medicaid expansion, and there are still those who do not qualify for Medicaid in their state and those who earn just enough that they are ineligible for the insurance tax credits available. Since minorities tend to be overrepresented among the poor, the flexibility of states to set their own eligibility criteria has implications for minorities' access to and quality of care. An estimated 4 in 10 uninsured African Americans fall into the coverage gap. Latinxs, who have the highest percentage of uninsured when compared to other racial/ethnic groups, are also affected.

Immigrants of all backgrounds face particular challenges under current health insurance laws. Those who are lawfully present are subject to a 5-year waiting period for Medicaid and CHIP, as well as exclusions from these programs for some classes of immigration status. States may waive the waiting period for pregnant women and children, but not all states choose to do so. Undocumented immigrants are further disadvantaged, as they are not eligible for Medicaid at all, are not eligible for tax credits used to make private health insurance more affordable, and are not eligible to purchase health insurance via the federal health insurance exchange. Lack of access due to not having insurance serves as a potential mechanism promoting service inequities. Not surprisingly, it has been argued that expanding insurance coverage for minorities would partly reduce inequities.

Low Reimbursement Levels and Provider Shortages. A major challenge for Medicaid beneficiaries is having a sufficient number of providers that accept Medicaid and CHIP payments. Alexander and Schnell find that increasing payments for new patient office visits reduces reports of providers turning away beneficiaries. According to their results, closing the gap in payments between Medicaid and private insurers would

Telegram: @medical_k

www.konkur.in

reduce more than two-thirds of disparities in access among adults. The implementation of the Mental Health Parity and Addiction Equity Act (MHPAEA) was expected to reduce the large unmet need for services. According to statistics by the Medicaid and CHIP Payment and Access Commission (MACPAC), only 35.7% of psychiatrists accepted Medicaid reimbursement rates as of 2019. Low participation of physicians is particularly concerning given the expansion of Medicaid to 85.3 million people in poverty.

Low reimbursement rates, payment delays, and billing requirements have been noted as a primary reason for not taking Medicaid patients in physician surveys. Systemically, providers within organizations serving large numbers of Medicaid patients may experience high expectations for productivity in order to make services financially feasible, which can increase provider burnout. There may also be a need for providers to spend additional time coordinating care for more vulnerable patients. The implementation of Accountable Care Organizations (ACOs), which bring together groups of providers and provide more flexible payment structures to incentivize positive outcomes, may be beneficial in reducing health care inequities. Expansion of safety-net providers such as Community Health Centers (CHCs), another provision of the ACA, is another avenue by which health inequities may be reduced due to their ability to promote screening, meet cultural sensitivity requirements, provide transportation assistance, and treat all patients regardless of immigration status or ability to pay. A review of mostly quasi-experimental studies from 2000 to 2017 found that greater funding for CHCs improved access to care (including mental health care), especially among low-income and racial/ethnic minority individuals. An additional consideration is that the long-term sustainability of CHCs is partially dependent on the revenue that they can continue to generate from patients, which is more challenging in states with high proportions of uninsured patients.

Children's Health Insurance Programs. CHIP is designed to make free or low-cost health insurance available to children without insurance but who are ineligible for Medicaid. As such, it plays a crucial role in reducing access barriers that create health service inequities among minority youth. In the first 10 years after CHIP was implemented, rates of uninsured children dropped from 30% of Latino children to 20%, 19% of Black children to 12%, and 17% of Asian, Native Hawaiian, and Pacific

Telegram: @medical_k

www.konkur.in

Islander children to 12%. A study of CHIP implementation in New York found that preexisting racial/ethnic inequities in access, unmet needs, and usual sources of care between white, Latino, and African American youth were virtually eliminated during the first year of enrollment. However, racial and ethnic minority children continue to be less likely to be enrolled in health insurance when compared to white children, even when eligible for CHIP, and disparities are substantial among Latinx children with immigrant parents. The Current Population Survey indicates that in 2018 the uninsured rate among Latinx children with only foreign-born parents (13.1%) was over triple the rate for non-Hispanic white children (3.8%) and 2.5 times higher than the rate among Hispanic children with at least one U.S.-born parent (5.2%). It was 4.6% among Black children.

In 2009, the Children's Health Insurance Authorization Act (CHIPRA) established provisions aimed at reducing health inequities, including providing outreach grants to increase enrollment, increasing federal matching rates for interpreters and translators, providing federal funding for medical care for immigrant children in states that waive the 5-year insurance waiting period, establishing quality of care measures to track health outcomes for children, and including specific provisions addressing health concerns that disproportionately affect low-income children and children of color. Across states that enacted the additional CHIPRA coverage for immigrant children, health insurance rates for this population increased by 14.5%, and unmet health needs decreased significantly.

Mental Health and Substance Abuse Parity. Laws aimed at achieving parity between insurance benefits for general health conditions and insurance benefits for mental health conditions have been enacted in various ways since 1996. In 2008, MHPAEA was passed, and the ACA subsequently expanded the reach of the act to more types of insurance plans. The MHPAEA does not require plans to offer specific mental health benefits but rather to ensure that the benefits offered are equal to those offered for other health conditions. Implementation of the law has been a complex process, resulting in final regulations being issued in 2013. While parity provisions are a promising step forward in access to care, it remains to be seen how the enactment of current regulations may or may not impact health service inequities. Poor behavioral health outcomes persist among people from minoritized, marginalized, and oppressed populations;

Telegram: @medical_k

www.konkur.in

thus, it is time for the model of care and advocacy in the behavioral health field to shift its priorities from parity to equity.

National Standards for Cultural and Linguistically Appropriate Services. Policies can directly address issues relevant to minorities. The National Standards for Cultural and Linguistically Appropriate Services (CLAS) were published in 2000 by the Department of Health and Human Services (DHHS) and revised in 2013. The CLAS standards provide guidelines for health care organizations addressing three areas: governance, leadership, and workforce; communication and language assistance; and engagement, continuous improvement, and accountability. These standards have been used to shape service delivery systems, as well as by some states to propose or pass legislation. Organizations are urged to provide trained interpreters, as well as linguistically and culturally adapted medical forms for non-English speakers. Among public mental health agencies in 43 states and Washington, DC surveyed in 2016, 10 had no policies corresponding to the 3 CLAS national standards, and 8 had policies in either 1 or 2 of the domains. Twenty-five agencies had policies in all 3 domains; only 8 of these had adopted all 15 CLAS standards. Improving communication within health care organizations and consistency of accountability measures may contribute to more widespread implementation. While the CLAS standards are not a federal law, failure to meet language access recommendations may be a violation of Title VI of the Civil Rights Act of 1964, which prohibits discrimination in organizations receiving federal funding. DHHS-funded organizations must provide meaningful access to services to non-English-speakers, including trained interpreters.

Policy Supporting Innovation. Policy changes can also facilitate the use of innovative strategies to address health inequities. In 2013, the Centers for Medicare and Medicaid Services adopted a regulation change allowing states to choose to reimburse for physical and mental health services provided by unlicensed providers, as long as a physician or other licensed practitioner has recommended the service. This opens a possibility for states to fill in gaps in service availability by engaging providers such as community health workers (CHWs) and other lay providers (e.g., addiction recovery coaches or peer support specialists). The use of lay providers to deliver mental health services has been successful in several major studies in underresourced communities within

Telegram: @medical_k

www.konkur.in

the United States. Further research is needed to examine the extent to which evidence-based interventions delivered by lay providers can increase equity in access *and quality* of behavioral health care.

Technology used to track the delivery of patient care and implement quality measures is another promising avenue via which to reduce health inequities. Advances in health information technology, including electronic medical records, have been a critical component of national health policies. The ACA calls for improved reporting requirements, while CHIPRA has promoted the development of standard quality measures as a way of tracking and addressing health care needs. The IOM noted in a 2009 report that more detailed information on racial, ethnic, and linguistic background collected in public health data systems would help target efforts to eliminate health service inequities. Little had changed by 2020 when many states' incomplete reporting of racial and ethnic data related to COVID-19 cases contributed to the overall delayed and inadequate response in addressing racial disparities. Combining detailed data collection with quality measures allows to identify gaps in care for specific groups and to respond with specific programmatic improvements.

In sum, the larger parameters of society shape the health care system. At the federal and state level, specific policies on health care, as well as economic policies and regulations, create a set of market forces. In turn, the nature of these health care system policies interacts with the contours of the community system to impact the experiences of ethnic and racial minorities. We describe both the intended and unintended consequences of these policies on health care organizations next.

Operation of the Health Care System and Provider Organization

As a result of the system-level factors described above, health care systems face differential costs and opportunities associated with treating ethnic and racial minority populations. As noted above, reimbursement by the state or the federal government holds a central role in shaping provider burden, service design, workforce diversity, and the organizational climate of health care organizations.

Cultural and Linguistic Competency in the Operation of the Health Care System. Health care policies designed to encourage cultural and linguistic competence, such as the CLAS guidelines, are expressly designed to counter discrimination. Yet, the ways in which a policy is

Telegram: @medical_k

www.konkur.in

implemented by organizations and providers impact client care. Language barriers for non-English speaking immigrant groups create major challenges in access to care. In one study alone, language barriers between provider and patient accounted for a $38 increase in charges for testing and increased length of stay in the emergency department. Patients who speak a different language from their providers report worse outcomes and higher dropout rates and may experience misdiagnosis or poor treatment based on misunderstandings in assessment. The use of interpreter services by competent providers has been shown in some instances to result in lower-quality care when the interpreter is not knowledgeable about mental health conditions or tries to make their own interpretations. However, a study of 452 Spanish-speaking patients seen for behavioral health visits in primary care found that interpreter use did not impact therapeutic alliance when compared to working with bilingual providers. Qualitative data from a subset of patients indicated a preference for working with bilingual providers when available, but found patients were satisfied with behavioral health care services delivered via interpreters and saw them as a way to increase access to care.

At the same time, improving linguistic competence within a system results in additional costs and time investment. Health systems may be reluctant or simply unable to cover these resources. Furthermore, even if willing, individuals may not be readily available or trained to fulfill the required services. Medical interpreters may not receive specific training in mental health care interpretation. Policy efforts such as state legislation based on the CLAS standards may be beneficial in reducing health inequities, but resources and training must be available to health care systems to finance and implement organizational change. A review of health care organizations' implementation of the CLAS standards suggested that barriers to CLAS implementation include a lack of awareness of the benefits of CLAS, perceived complexity of implementation, and organizational resistance to change. Recommendations identified across studies included providing sufficient language access services (i.e., professional interpretation and translation); ensuring data collection on race, ethnicity, and language as related to patient services; and obtaining buy-in from leaders and administrators. Community engagement, workforce development and training, and strategic implementation across all organizational levels were also highlighted.

Telegram: @medical_k

www.konkur.in

Integrated Health Care. The integration of behavioral health services into the primary care setting has been advanced as a strategy to improve behavioral health outcomes for minority populations, given studies that indicate that members of racial and ethnic minority groups are more likely to seek mental health care via their primary care providers (PCPs). Yet, only limited data are currently available on how to best implement high-quality behavioral health services for minority populations in primary care. Studies have found that PCPs are less likely to detect mental health concerns among racial and ethnic minority patients compared to white patients. The pressure to treat behavioral health challenges in the time-limited setting of primary care, in addition to constraints in specialty care options available for PCP referral, may result in situations in which clients are offered lower-quality services or do not follow up on treatment. One study found that Latino primary care patients diagnosed with depression were more likely to follow up on and complete treatment via medication alone, despite the majority of the patients expressing a preference for psychotherapy over medication. These patients were able to access medication directly via their PCP but may have experienced challenges in accessing therapy services.

Research on models of integrated and collaborative care, as well as their impact on specific racial and ethnic minority populations, is needed in order to explore how this approach may or may not reduce health service inequities. As one of the most studied models of integrated care, collaborative care shows promise as a strategy to reduce inequities. A review of studies of collaborative care for depression among limited English proficiency patients (LEP) concluded that collaborative care delivered by bilingual providers was more effective than usual care. Weaknesses in the evidence base included a low number of studies (particularly for languages other than Spanish), lack of information about whether cultural adaptations were made in addition to language adaptations, and lack of research examining why LEP patients are less likely than English-proficient patients to be enrolled in collaborative care programs. A review of collaborative care for racial/ethnic minority patients similarly found it to be a promising approach to improve depression outcomes but found that studies encountered challenges in recruitment of racial/ethnic minority patients.

In other ways, the design of health care systems and services contributes to inequities. When health care organizations do not offer

Telegram: @medical_k

www.konkur.in

effective treatment for behavioral health problems, issues such as alcoholism, substance dependency, or posttraumatic stress disorder affect health status directly and compound other health problems indirectly. Further, offering a service-level spectrum, whereby good quality health services are offered for services that attract the healthy, but poor-quality services are offered for the sick or those with chronic conditions (referred to as “adverse selection”), tends to discourage use and hinders good outcomes.

Organizational Climate and Institutional Racism. Outcomes research has demonstrated that the climate of attitudes and beliefs and culture (both normative expectations and actual behaviors) in the provider organization toward minoritized populations affects the receipt of quality care. For example, epidemiologic evidence indicates that racial and ethnic minority patients have lower rates of mental health disorders overall but higher levels of severe illness and a lower likelihood of receiving mental health care, reflecting structural inequity. As a result, racial and ethnic minority patients may come to mental health and substance abuse care at higher levels of illness severity and terminate treatment early. This may reinforce a cycle of bias and discrimination, in which providers view patients as requiring more resources and intensive treatment or are seen as typically less adherent. In addition, these patients may also require referrals and networking with other social and service agencies—work for which the health care provider is not compensated. Rather than recognizing structural racism as a root cause of these inequities, providers may maintain negative attitudes towards patients or ascribe cultural explanations to structural conditions. Structural competency has been advanced as a paradigm shift in medical education and practice, away from a focus on stigma and cultural competency towards a focus on recognizing how structures, including social and economic forces, shape clinical interactions and how these conditions in turn call for structural interventions. At the organizational level, the use of evidence-based strategies for organizational change, such as the ARC (Availability, Responsiveness, Continuity) intervention model, may be an avenue by which to change organizational attitudes. In this model, “change agents” are trained to educate providers, advocate for systems-level change, provide implementation data and feedback, and facilitate communication within the organization and with the broader community.

Telegram: @medical_k

www.konkur.in

Design of Services for Minority Groups. While the evidence is inconclusive on whether the lack of targeted services for diverse patient populations plays a central role in service inequities, a meta-analysis showed that culturally appropriate interventions were four times more effective than those not targeted to specific cultural groups. Further, interventions conducted in the client's native language were twice as effective as those conducted in English. Yet, there is a serious shortage of culturally appropriate behavioral health services for ethnic minority youths. In a review of psychosocial interventions, Pina and colleagues found that there were no well-established interventions effective for treating trauma or stress reactions, self-injurious behavior and suicidality, or comorbid disorders or multidisorders among ethnic minority youth. There is also a need to address the disproportionately high rates of suicidal behavior and homelessness among BIPOC youth who are LGBTQ. Policies cocreated in partnership with these youth are likely to be more effective in meeting their needs.

Structuring for racial and ethnic concordance or matching between patient and provider is one area of heated debate. Race concordance for African Americans has been associated with higher patient participation in decision-making and greater satisfaction with care. Patient–provider matching also tends to improve retention of clients and intervention outcomes and may increase entry and adherence to treatment. If this is, indeed, the case, professional services in culture-specific clinics might be a tool for providing better services to ethnic minorities. However, there is limited evidence on whether or not they reduce service inequities. While ethnic similarity may facilitate retention in therapy, it may have only a minor role in therapy outcomes. Similarly, physician's race concordance with patients does not appear to be associated with either the use or quality of care, only with preventive care.

Clients are likely to respond to the therapy in ways that are consistent with their cultural socialization regarding care. Therefore, culture most likely defines the options perceived to be available, useful, and/or desirable behaviors of what is culturally expected of the therapist and client roles. Patient preference for one theoretical orientation over another might characterize members of cultural groups. Researchers hypothesize that therapists and clients who are ethnically similar may be more analogous in terms of problem perception and attitudes about coping and treatment goals, and some studies have found that patients delay

Telegram: @medical_k

www.konkur.in

treatment based on the perception that an ethnically dissimilar clinician will not understand their needs. As a result, these coinciding factors may improve the effectiveness of therapist/client interactions.

This is not to say that all racially/ethnically concordant patients and providers will share the same attitudes and beliefs. Research has demonstrated that *cognitive* match between patient and provider is most important, with evidence of this significance persistent even after controlling for ethnic match and the client's language preference. These findings have implications for practice/training and for the need to assess discrepant orientation and treatment ideas. Across studies, reasons for patients not initiating treatment included interpreting that the mental health system could not help them, the belief that somatic symptoms were not related to mental health conditions, and stigma (though interpretations of stigma varied). Reasons for not continuing treatment included feeling discomfort discussing emotions with strangers, preferring a particular clinician communication style, and having concerns about clinician power and authority.

Provider-Level Factors

Use of Guideline Concordant or Evidence-Based Treatment. Providers' reluctance to adopt evidence-based treatments (EBT) when serving minorities has been well-documented, leading to service inequities. The question remains as to whether the deviation from EBT is greater among providers who serve primarily ethnic and racial minorities or whether providers are less likely to provide EBT to their minority clients. Evidence has been found for both; clients who are poor or African American and Latinxs have been found to be less likely to be offered the more rigorous or intensive care options provided to those who were more advantaged, but also facilities serving mostly ethnic and racial minority patients were less likely to offer evidence-based care. For example, a study of services received by low-income adult patients with anxiety disorders in a community mental health center found that the majority of patients received pharmacotherapy, and that of the minority receiving psychosocial treatment, they were receiving supportive therapy rather than the established evidence-based practice of cognitive-behavioral therapy (CBT). Only 3.8% of patients with an anxiety disorder received the most effective treatment, exposure-based CBT. However, many health

Telegram: @medical_k

www.konkur.in

care institutions do not provide sufficient support for providers to adopt quality behavioral health care within the pressures for productivity.

Research examining the use of medical procedures across chronic illnesses, such as depression, has consistently found a lack of referral of minorities for EBTs when compared with non-Latino whites, even when minorities meet clinical appropriateness criteria for EBTs and when age, gender, and insurance status are controlled. Although longitudinal studies examining changes in trends for inequities in EBT among Medicare-managed care patients indicate that racial inequities in EBT have declined for some illnesses, for mental health care, the gap in EBT for minority patients remains.

Provider's Attitudes and Perceptions: Uncertainty, Stereotyping, and Bias. Providers seldom receive training issues surrounding stigma, either in the community system or in the health care system. As a result, there is reason to assume that they carry the prejudices of the communities they live in and the health care systems in which they work. Stigma attributes causes of behavior (genetics, socialization, character), assign characteristics to individuals (e.g., violent, unintelligent), and ascribes beliefs about health behaviors (noncompliant) that are embedded in individuals, organizations, and places. Stigma interferes with how the problems of ethnic and minority group members are conceptualized, how treatments are planned, and what expectations are held for recovery. From the start, providers do not have the cultural tools to motivate minority patients to voice their symptoms, treatment concerns, or preferences. Providers display fewer patient-centered behaviors, are less receptive to question asking, and tend to demonstrate greater verbal dominance with minorities than with white patients. This can lead to miscommunication and misunderstanding between the patient and provider, resulting from cultural or language differences. In turn, this contributes to uncertainty in the clinical encounter, which is well documented to increase provider hesitancy in treatment which may manifest in disparities in clinical decision-making, treatment planning, care provided, and outcomes. When cultural differences have diagnostic implications for clinical symptoms or for signs or tests due to atypical symptom presentation, providers have incomplete information about the efficacy of a therapeutic intervention. This is not surprising because research on these deep cultural differences is not supported or regarded

Telegram: @medical_k

www.konkur.in

as highly as standard treatment-based research, and, even in the latter, minorities are under-represented in clinical trials.

Stereotyping of minoritized patients by health care professionals, documented in a number of recent studies, is another potential source of service disparities. Even if stereotyping stems from unconscious bias, reflecting limitations in cognitive mechanisms, the effects on inequities are real, nonetheless. Categorizations such as race, age, sex, and socioeconomic status are overgeneralizations and produce statistical discrimination, which goes directly against the more tailored precision approaches. For example, providers tend to see Black patients as less educated than non-Latino white patients. Providers' implicit bias has consistently been linked to worse perceptions of interactions with health care providers among African American patients. Finally, provider-based biases have also been posited as negatively influencing clinical decision-making.

Both over and underdiagnosis could result from these stereotypes and negative biases. Overdiagnosis occurs when appropriate behaviors in one culture are interpreted as pathologic by a professional from another culture. Incorrectly diagnosing a psychotic disorder where none exists could result in inappropriate hospitalization or in the use of potentially dangerous antipsychotic medication. For example, in more extreme cases, certain cultural or religious beliefs and practices common among Latinxs and African Americans accept, and sometimes encourage, visual and hearing perceptions of supernatural experiences, which are interpreted by professionals in the dominant culture as pathologic hallucinations. In an epidemiologic study in Puerto Rico, 13% of the population reported some kind of hallucination. Yet, a qualitative analysis of these symptoms by trained local psychiatrists revealed that they occurred mostly in the context of religious or spiritualist experiences and were not pathologic. Not surprisingly, recent epidemiologic and clinical research has raised questions about the relationship between the endorsement of psychotic symptoms and the diagnosis of psychotic disorders among culturally diverse groups.

Underdiagnosis occurs when clinicians ignore genuine manifestations of mental illness, misguided by a misinterpretation of cultural sensitivity. The absence of cultural and contextual information contributes to an elevated probability of misdiagnoses and inappropriate treatment formulation. A growing body of research has documented that minority

Telegram: @medical_k

www.konkur.in

patients were more likely to report that their provider did not discuss end-of-life care and were less likely to receive recommendations for how to quit smoking or engage in diet and exercise. Providers may unintentionally or intentionally dismiss minority patients' concerns or may not communicate about health promotion, psychoeducation, or early screening for mental disorders. Only one-quarter of Latinxs surveyed in the National Latino and Asian American Study reported ever being asked about alcohol or drugs. Fewer than 20% of Latino patients reported ever being asked about emotions, nerves, or mental health problems. This limited inquiry may lead to missed opportunities for early identification of mental health or substance use disorders and a lack of referral to specialty services.

Clinician Training in Cultural Responsiveness. The concern with provider-based bias does not translate into the notion that there are no beliefs in ethnic and racial communities that interfere with treatment. In a recent study on COVID-19 vaccination intentions, the fact that individuals from diverse racial and ethnic groups worked in a health care setting did not offset disparities. Asian, Black, and Latinx individuals, as well as those who identified as multiracial, expressed a lower likelihood of vaccine uptake. This provides a clear caution about assuming the health stance of individuals based on relevant sociodemographic categories. While cultural responsiveness training has been offered as a solution to the problems described above, it is not yet an integral part of the education of many health professionals. Health care personnel typically have limited training in the cross-cultural formulation and cultural humility, leading to a lack of concordance in defining the problem and treatment goals. There is also evidence that providers signal their expectations about patients' outcomes and whether they believe there will be improvements, which may be related to actual patient health outcomes. For example, health care professionals may communicate lower expectations of treatment outcomes for socially and economically disadvantaged patients, which could discourage minority patients and lead to poor outcomes and low treatment retention. Furthermore, clinicians and researchers have called for a move beyond cultural competency to structural competency, calling for increased focus in medical education and health care practice on understanding how social, economic, and political forces, including structural racism, produce downstream health care conditions.

www.konkur.in

THE COMMUNITY SYSTEM

Community systems differ dramatically in a series of characteristics that both can facilitate the use of services and offer protection against health problems. In the SCF, the community is defined as “a group of people with a similar cultural origin and diverse characteristics that are linked by social ties, share common perspectives, and engage in joint action in geographical locations or settings.”

Environmental Level

Neighborhood context influences both individual health and health behaviors. Residing in socioeconomically disadvantaged neighborhoods has been linked to poor health outcomes due to built-in environment factors (e.g., increased exposure to pollutants and decreased access to green spaces); limited access to health care facilities and health care providers; poor quality of available health care; stress related to poverty and neighborhood violence; limited opportunity for economic mobility; disproportionate contact with the criminal legal system; and decreased social connectedness. These circumstances are not accidental. Political policies, such as redlining predominantly Black neighborhoods, decreased residents’ access to secure mortgages and opened up their neighborhoods to natural risks (e.g., flooding).

The geographical area in which minority populations live helps to create a social context which, in itself, fosters a lack of connection with treatment systems and the dominant culture. Geographical segregation continues, perhaps even at greater levels than would be expected for minority populations. In a nationwide study of data from over 25 years, Chetty et al. found the black–white gap in income mobility persists even among boys who grew up in the same neighborhood. Fewer than 5% of Black children grow up in low-poverty neighborhoods, which also have low levels of racial bias among whites and high rates of father presence. Members of immigrant groups have a variety of experiences with resettlement depending on the time period in which they arrived in the United States, the circumstances of entry, and the political and social climate towards the particular group at the time. Thus, the social context and the geographical context are often intertwined and overlapping. This impacts health on multiple levels, from the prevalence of particular

Telegram: @medical_k

www.konkur.in

conditions to access to and use of mental health and substance abuse services.

Level of Social Cohesion

Community social cohesion may play a role in health inequities by influencing factors that affect service outcomes. For example, there is evidence that organized and cohesive communities are able to ensure that state budget cuts do not affect their community and this, in turn, allows them to maintain increased access to funding for health and education. Neighborhood social cohesion has also been associated with greater use of preventive health care services. Beyond service use, social cohesion may impact health outcomes more directly as well—it has been shown to moderate the impact of neighborhood built environment (e.g., structural disadvantage, urban green space) on mental health.

Social Capital and Social Networks

While it is difficult to draw a clear line between the “community” as “place” and the “community” as “people,” the difference is important. While a place can shape the personal connections that individuals have, social scientists also focus on the community as individuals’ “small worlds”—that is, the actual nature of social ties and social interactions that individuals have in a geographic area. Family, friends, and even casual contacts can recognize a problem, may facilitate or inhibit help-seeking, and may influence adherence in future medical contacts, filling prescriptions, and adhering to lifestyle advice. Community ties shape how people recognize, interpret, and guide an individual’s reaction to the onset of mental health and substance abuse problems. They also continue to exert influence throughout the entire illness career. That is, not only do social networks constitute individuals’ “community of meaning,” but they are also their “community of influence.” Research has found social networks to play a key role in whether individuals deal with mental health and substance use problems or dismiss them, whether they rely on the family alone or seek professional help, and whether they are welcomed back into the community or rejected. All considered, social networks are critical in the course and outcome, especially in recovery from substance use disorders. For individuals from cultures that are wary of the formal treatment system and who are immersed in a strong family system, this can result in delays in care and/or the burnout of their social networks. However, when the

Telegram: @medical_k

www.konkur.in

health care system has a known concern for and tradition of understanding the population groups under their purview, social networks can facilitate care, communication, and recovery.

Service systems working with minoritized families need to consider the important role of extended family and “fictive kin,” that is, individuals who are not related by marriage, birth, or adoption but who are also possible sources of support or burden in treatment. For example, in strong and tightly meshed family networks, such as those of most Latinxs, African Americans, and Asians, individuals may initially be discouraged from seeking professional health services, feeling that the family should handle the situation. Only when family support systems are lacking, or become ineffectual in handling a crisis, do some culturally diverse families turn to professional help, even then activating social networks contacts to find trusted sources of care. Yet family support and supportive social networks have also been commonly shown to *facilitate* service use among African American adolescents, particularly when caregivers have had positive experiences with mental health services and/or refer their children.

Access to mental health services is a *process* that is relational and socially embedded. One way that nonprofessional support can lead to formal support is through group social identification. Self-identifying as a person with a mental illness or addiction and identifying with other people who have the same condition can promote professional help-seeking, in part by reducing stigma. Innovative strategies that leverage the influence of community networks can facilitate health and health care. Certainly, the role of churches and community centers in African American neighborhoods has been leveraged as a way to reduce vaccine hesitancy during the COVID-19 pandemic, as was the case for HIV education and testing. Trusted community organizations offer a way to embed health care services in the settings in which individuals and families naturally seek help.

Individual Factors Other than Need or Clinical Appropriateness

General Education. The number of years of schooling is directly linked to the development of effective capabilities that influence subsequent life conditions that have an effect on health, including economic welfare, healthy lifestyles, and full-time employment. Higher rates of education have been shown to positively impact mental health by increasing one’s resources to cope with adversity or increasing a sense of control over

Telegram: @medical_k

www.konkur.in

one's destiny. Low educational attainment is not only a strong predictor of poor mental health and substance abuse outcomes for children but remains significant for mid-age and older cohorts.

Health Literacy and Numeracy. Health literacy has two components—knowledge of health issues and knowledge of what to do if a health problem arises. The first is a skill involving both oral and written communication that may or may not be related to educational attainment. It is a twofold concept that includes the individuals' basic literacy skills and the application of those skills within the health care system. A related concept, health numeracy, involves not only understanding mathematics but also quantitative concepts such as "reduce/increase." The IOM has highlighted that health literacy is not solely an individual skill; rather, it results from the interaction between individual capacity and the demands of the health care system. It can also result from what "others" around individuals know. Inequality in educational opportunities and resources also contributes to why public health researchers conceptualize health literacy as a "midstream" determinant of health.

Health literacy may indirectly create barriers to health care use by inhibiting access to care due to a patient's inability to register for health insurance; difficulty in interpreting coverage benefits and rules; avoidance or delays in accessing health services due to the inability to adequately fill out forms in physician offices or difficulty following directions to service facilities. Once individuals with poor health literacy enter care, they face inequities in health outcomes associated with literacy limitations, with people who read at lower levels being 1.3 to 3 times more likely to experience adverse health outcomes than individuals with high literacy levels. They are also more likely to report poor health, have an increased risk of hospital admission, and have incomplete understanding of their health problems and treatment.

On the second dimension of health literacy, awareness of relevant resources, inequities in health care among some racial and ethnic minority children appear to be linked to parental knowledge of the disorders and available treatments. Zuckerman and colleagues have found that compared with non-Latino white parents, parents who were Latino or other ethnicities had less familiarity or personal experience with developmental disabilities, like Attention Deficit and Hyperactivity Disorder (ADHD) and Autism Spectrum disorder (ASD). One study suggests that

Telegram: @medical_k

www.konkur.in

parents' level of English proficiency and parents' knowledge about ASD are related to disparities in Latinx children's ASD diagnosis and treatment in the United States. There is also evidence that different ethnic groups in the United States have varied perceptions of what is considered a mental health problem in their offspring. In one study, Latino and African American parents rated their adolescents' mental health and life satisfaction as better than their non-Latino white counterparts and overall perceived fewer emotional or behavioral problems in their children. These differences existed even after adjusting for the clinical needs of the child, the child's level of impairment, and the sociodemographic characteristics of the parents. Thus, while a lack of knowledge about a problem may lead to health inequities, it is also possible that different perspectives on a situation may lead to different patterns of seeking care.

Negative Provider Stereotypes. Patient views of providers may prove to be influential factors in causing inequities for racial and ethnic minority populations. For example, research revealed that individuals holding strong negative stereotypes of physicians are more likely to delay care or only seek treatment once symptoms become severe or impede daily functioning. Therefore, if delays in treatment are due in part to negative stereotypes, service inequities in illness prevention or early intervention may emerge. Negative stereotypes of physicians may result from patients' own history of negative treatment in care or the distrust many minorities feel towards the health care system. However, recent population-level research in the United States has documented very high endorsement of general and specialty providers for unlabeled situations that meet DSM criteria for psychiatric diagnoses of schizophrenia or depression. While there were few, if any, differences between majority and minority group populations, the response to individuals with alcohol dependence revealed continued and even increasing stigma.

Patient's Competing Needs. Some ethnic and racial minority patients may come from low-income backgrounds with complex social needs. Lack of access to paid sick leave, inflexible work scheduling, irregular hours, lack of transportation or unreliable transportation, and difficulty obtaining childcare all pose additional challenges to utilizing health care services. Studies have found that these barriers account for both missed appointments and lack of follow-through on specialty referrals.

Telegram: @medical_k

www.konkur.in

WHEN HEALTH CARE SYSTEMS AND COMMUNITY SYSTEMS MEET: MECHANISMS PRODUCING INEQUITIES

Taken together, inequities arise when disadvantages in the health care system interact with those in the community. At each level, the SCF suggests that six fundamental mechanisms produce inequities for minoritized populations. These are represented as the center stream in Figure 56.7–1. While they link with causes of inequities, they also suggest points of intervention. They represent potential leverage points for systems, providers, and patients to change the health care system, existing policies, clinical training, and community programs. Below, each interface between community and treatment systems is explored.

1. Failure of health care markets, institutional bias, and limited financing leading to decreased access to and utilization of mental health and substance use services. State and federal regulations aimed toward cost control also contributed to the increase in the number of uninsured or underinsured. For example, individuals are typically excluded from Medicaid as states respond to increased costs by enacting more stringent eligibility criteria. Yet, the expansion of public insurance programs and subsidized private plans to low- and middle-income individuals offered under the ACA can increase access to care. Nonetheless, some minority groups may confront other hurdles to getting insurance, such as lack of citizenship or documentation status, or may still have difficulty paying for subsidized coverage, leading to a lack of insurance or underinsurance. While health insurance coverage facilitates access, it is not a sufficient condition for ensuring behavioral health care since lack of available appointments is a serious barrier to mental health and substance use treatment. The low number of mental health and substance use providers accepting Medicare and Medicaid reduces access to quality care for low-income and vulnerable populations. However, other factors such as increased HMO penetration, augmented provider supply, and the presence of a community mental health center in neighborhoods of color have been shown to reduce service inequities.
2. Differential pathways into services leading to differential experiences of service, delayed utilization, no service, or inadequate service. Language barriers can lead patients to drop out of care, opt for

Telegram: @medical_k

www.konkur.in

alternative services, or delay care. Inaccuracies in assessment can also result in mistreatment or misdiagnosis of minority patients. There is mounting evidence that minority patients receive lower quality treatment and receive treatment for a shorter period of time. For example, white youth are more likely than minority patients to receive adequate care following a major depressive episode, while minority youth are less likely to be prescribed psychotropic medications, even after adjusting for need factors. Equally importantly, the larger cultural context determines how similar social networks can facilitate or delay treatment. Competing demands on time from work and childcare for minority parents may constrain minority families from engaging in treatment, given more urgent matters.

Thus, differential pathways into services may represent a key mechanism leading to service inequities among racial/ethnic minorities, with lack of patient problem recognition, differential referral and treatment by providers, and barriers to care serving as potential precipitating factors to inequities. Noting the insufficient attention to dynamics of pathways to treatment, Alang and McAlpine found that individuals who were “ordered” into care (i.e., followed a coercive or heavily recommended pathway) either for a mental illness or substance use disorder were less likely to rate treatment as effective compared to those who made an independent decision. Not surprisingly, they also found that individuals who are ordered into care are more likely to be African American (86% more likely) or Latinx (twice as likely), with the former significantly less likely to report effectiveness. They conclude that pathways to care reflect differential positions in the social hierarchy.

Other pathways result in inequities that may have both short- and long-term effects. For example, Latino and African American children are overrepresented in the juvenile social service sectors. They receive fewer therapeutic services compared to clinically comparable white children and remain longer in services. As a result, data analytics are being used to detect patients at risk of receiving lower-quality care based on demographic and illness-related factors, and payment systems used to incentivize providers for providing high-quality care to these patients. Nonetheless, there is considerable debate over the utility of pay-for-performance measures in achieving specific goals at the level of hospitals and the health system as a whole. ACOs may help eliminate inequities by rewarding health care

Telegram: @medical_k

www.konkur.in

systems for efficient use of resources and positive outcomes and penalizing them for inefficiency and poor results.

3. Poor patient–provider interaction leading to miscommunication, clinical uncertainty, low therapeutic alliance, stereotyping and clinical errors. Patient–provider match and expectations for a visit are important in determining treatment outcomes. However, attempts to address research documenting problems arising from poor patient–provider interaction have inadvertently produced additional problems. Ethnocentric models of health service delivery may overpathologize minority behaviors that differ from those of the majority culture. Racial and ethnic minority patients report being treated with disrespect or being looked down upon more often than non-Latino white patients. The critical link to inequities lies not only with what happens in the clinical encounter but with the resulting effects on the patient's utilization of health care and on the advice they offer to others in their lay network. For example, patients who reported being treated with disrespect were less likely to go for a routine physical exam within the last year, to have received optimal care for a chronic condition, and to have followed their doctor's advice.

   Patients may also have different expectations of treatment and provider behavior that impede effective communication. A number of studies have reported that differences in race and ethnicity between patients and their providers can present barriers to effective communication and partnerships for care. Inequities resulting from barriers to effective communication between racially/ethnically mismatched patients and providers include: discordance in the understanding that patients and providers have regarding disease causation and effectiveness of treatments, significantly lower reports of physician participatory decision-making styles by minority patients as compared to nonminority patients, and lower rates of receiving preventative and necessary medical care among Black patients with non-Black physicians compared to Black patients with Black physicians. These examples demonstrate that patient–provider match and expectations for a visit are important in determining treatment outcomes.

4. Mismatches in mental health and substance use service offerings and minorities' services needs and living circumstances leading to dropout and low or no service use. Services inequities have been linked to higher disability and greater disease burden in minority populations.

Telegram: @medical_k

www.konkur.in

One of the mechanisms by which service inequities take place is through the mismatch of services to the patient's needs. As we described earlier, there is substantial evidence of the potential for clinicians to engage in "statistical discrimination"—that is, to incorrectly assign a classification or social categorization to a patient that aligns with negative stereotypes, particularly when the patient's request or symptoms are ambiguous. Under such conditions, clinicians may inadvertently incorporate attitudes and beliefs from prior clinical encounters or common stereotypes. This may lead clinicians to disregard individual data and consequently mismatch services to needs. This mismatch of services to needs can result in decreased utilization of and access to health services and health resources as well as differential outcomes in health and greater disease burden. In the absence of cultural and contextual information that supplants stereotypes, there is an elevated probability of misdiagnoses and inappropriate treatment formulation. Minoritized populations are more likely to have nonconcordant psychiatric diagnoses in psychiatric emergency services and to be undetected for mental health disorders in primary care. Research reveals that symptom presentation varies across racial and ethnic groups and can differ from what most clinicians are trained to expect. Not surprisingly, racial and ethnic minority patients are less likely to be offered "talk therapies" such as counseling and tend to be prescribed higher drug dosages than their white counterparts.

Dissimilarities in the typical conditions in which many minority populations live as contrasted to their providers (i.e., including poverty, lack of economic opportunity, food insufficiency, inadequate housing, social exclusion, low access to educational opportunities, and unsafe neighborhoods) can lead to social inequality that needs to be tackled by the health care system. As such, there has been a call for health equity research that prioritizes multilevel interventions, addressing structural and contextual factors at the community, organizational, and individual levels. Multilevel interventions to amplify social connection in minority neighborhoods could increase behaviors that have a positive or protective effect on health, such as exercise, expansion of social networks, and better problem-solving.

5. Lack of community trust and erroneous expectations of services leading to disengagement and poor collaboration in health care service systems. Local perceptions of health services affect utilization and

Telegram: @medical_k

www.konkur.in

depend on prior experience with the provision of services and the efforts that the local service system has made to understand and adapt to the cultural and need demands of its clientele. Studies, including a qualitative analysis of an Afro-Caribbean community, revealed that their experience of mistreatment and social exclusion by health professionals reverberated on future utilization and on community sentiments toward the mental health system. In addition, African American families report fearing that their children would be institutionalized and express this fear as an important reason for not taking their children to treatment. Repeated negative contacts with the health system or with a lack of trust in key gateway providers such as teachers result in community-held beliefs that decrease help-seeking and produce health service inequities for minoritized populations.

6. Limited workforce availability and training of service providers to treat ethnic and racial minority youth leading to reliance on informal or poorly trained providers. The disproportionately low geographic supply of providers, particularly multilingual service providers, in communities with ethnic and racial minorities as compared to nonminority communities translates into market failure to provide more and better-quality care to minorities. For example, communities of color have been found to be four times more likely to have a shortage of providers, regardless of community income. Low reimbursement rates from public and private payers can lead to a shortage of services and provider burnout. Health care organization arrangements for distributing providers to minority Medicaid beneficiaries have also been suggested to be influential in-service inequities. Only 7.8% of psychologists, 12.9% of social workers, and 21.4% of psychiatrists are from racial/ethnic minority groups. Medicaid beneficiaries, particularly those with limited English language skills, may not be able to access physicians with a high caseload of privately insured patients.

Communities with high proportions of black and Latino residents were four times as likely as communities with non-Latino whites to have a shortage of physicians regardless of community income. In parallel, health care services available through the Indian Health Services vary widely across tribes. The Indian Health Services partially offsets the lack of insurance for some uninsured American Indian and Alaska Natives (AIANs), but important needs are left unmet. This is problematic since AIANs were more than two times as likely to be uninsured than non-Latino whites. These findings have led to the conclusion that the elimination of

Telegram: @medical_k

www.konkur.in

racial/ethnic health inequities is an issue of distributive justice which entails redistributing valuable material resources and opportunities to those in the lower echelons of society.

In sum, the interaction of the health care system and the community system at different levels produces a mismatch in cultures—not only the culture of medicine and the culture of everyday life but in the mismatch of dominant cultural ideas and those that may be unique to minoritized populations. Oftentimes, the beliefs of both patients and providers are based on generalized cultural beliefs and do not cut through those prejudices to get to individualized care. Equally important, both actual experiences and a family's, provider's, or community's experiences can produce a view of treatment that limits the receipt of effective care.

FUTURE DIRECTIONS: RESEARCH AND INTERVENTION

The SCF is intended to help conceptualize and carry out research directed at eliminating ethnic and racial inequities, to assist in the training of health and social agency personnel, and to supply service planners and policymakers working hypotheses, initially, and a science-base, eventually, on how to intervene and eliminate service inequities. As evidenced from our review of extant theory and research, traditional service models should be restructured in order to reduce service inequities for racial and ethnic minority populations.

However, it is important to understand the role of a framework and the difference between a framework and a model. As Nobel Laureate Elinor Ostrom pointed out, theory provides an understanding of a complex whole. A framework brings together extant findings from different branches of science to provide a picture of how the entire system operates and what are the key subsystems and factors at work in each subsystem. Doing so is complicated because different disciplines have their own very different frameworks, theories, and models that they employ to understand their parts of the complex system. But without an organizing whole, findings are not likely to cumulate, discrepant findings are not explicable, and unintended consequences in translation to policy and programs are more likely.

The framework, as an organizing picture, must be translated into a testable model for the particular problem at hand and the research

Telegram: @medical_k

www.konkur.in

question to be answered. The framework offers an overview of potentially relevant variables to be considered, orients researchers to issues in research design, data collection instruments and approaches, fieldwork protocol, and even potential analytic strategies. For example, a complex population systems framework aligns with the current discussion of the utility of multilevel modeling. This is a relatively new tool that now allows the consideration of different contexts in the same analyses. This is important because when there are nested levels (e.g., samples of individuals who live in different cities), these specialized analytic approaches, for example, correct for the violation of independence of cases assumed in regression analyses. Without these corrections, the determination of statistical significance is off. However, the data requirements to be able to analyze the effects of different contexts are very high, requiring a large number of contexts (e.g., neighborhoods, counties) at the higher level. It would be impossible, or nearly so, to develop a feasible research study that could incorporate everything in a framework.

That said, from the SCF, we posit six mechanisms that form a foundation for rethinking intervention strategies: (1) increased client/patient activation/empowerment; (2) information exchange between client and provider; between systems and communities addressing social networks rather than individuals alone; (3) new and/or different policies to increase access to services and quality of services; (4) better treatment matching; (5) restructuring of service systems to reduce reliance and action based on stereotypes, prejudice, and clinical uncertainty; and (6) quality collection of data on racial and ethnic disparities to improve system accountability.

1. **Patient activation.** Patient activation, defined as learning the knowledge, skills, attitudes, and self-awareness necessary to have greater decision-making and efficacy in health care behavior, has been associated with improved health behaviors such as exercise, disease self-management behaviors such as adherence to drug regimens, and an array of health outcomes including improved mental health. There is evidence that patient activation enables patients to take more charge of their health behavior, elicit more information from their provider, achieve greater satisfaction in the clinical encounter and better outcomes and increase engagement and retention in care.

Telegram: @medical_k

www.konkur.in

2. **Information exchange.** Information exchange is based on a dialogue between patient and provider or between community and health service system so that the provider learns about the social context (i.e., where patients live, what they do, what matters to them, their social position, and their environment and cultural perspective of the patient). There is evidence that information exchange promotes a more egalitarian view of the information needed for a patient-centered encounter and to structure treatment recommendations or proposed behavioral changes acceptable in the patient's daily lives. If service use and provider action depend on a social influence process in the community as well as individual predispositions as has been documented since the 1970s, then understanding and using effective diffusion methods are likely to be more effective and efficient.

   However, information has a larger system component as well. Further, a recent *JAMA* editorial laid out the role of technology, especially the digital divide, in the differential rate of vaccination between minority and majority populations and among age groups. They noted that while there have been important recommendations offered to promote equity in the distribution of COVID-19 vaccines, they have missed the information component, which requires not only information and skills to sign up and do so quickly, but a recognition of the gaps in home-based broadband (40% among older people) and the greater likelihood of dead zones in minority communities. Yet, national guidelines and expert recommendations have neither considered nor proposed solutions to technology-related equity challenges.
3. **Policies.** Policies include decisions by organizations such as routinely providing assistance to patients in communicating with their providers or regulations by governments or public authorities such as deciding eligibility criteria for Medicaid services. Recent research has demonstrated the larger health effects of policy changes that are critical for disadvantaged populations. When the U.S. Department of Agriculture mandated that the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) move from a paper voucher to an electronic benefits transfer (EBT) debit card, participation in this program increased substantially (7/8%). This was, even more, the case in states that heretofore had the lowest WIC participation rates. This has direct implications for health. Research has clearly documented that WIC improves health outcomes for pregnant women,

Telegram: @medical_k

www.konkur.in

infants, and young children. An example of a policy change could be a new requirement that interpreter services be readily available in the clinical encounter if English is not the primary language of the patient. Another policy to increase equity could be mapping areas where few mental health providers accept public insurance programs to provide additional incentives (i.e., higher reimbursement rates) for providers to offer care in those areas.

4. **Better treatment matching.** Better treatment matching includes the provision of linguistically appropriate services as well as treatment and outreach options that are socioculturally compatible with the circumstances of the target population. There are three basic criteria on which to judge whether there is treatment matching of services: the treatment/services are based on the cultural values of the groups of interest; the strategies involved in the treatment/services are congruent with the culture and context of the particular ethnic/racial group, and the components of the service/treatment strategy are based on the expectations and behavioral preferences of the ethnic/racial groups. It is argued that the treatment matching of the services/treatments with the patient/community is necessary for quality improvements to be institutionalized and sustained by the service organization and acceptable to the community.
5. **Restructuring of services.** Restructuring of services involves an organizational change to better accommodate the needs of clients. Settings that are accessible to communities and which they trust (i.e., community-based organizations, churches) might be more acceptable as settings for health or mental health service delivery or outreach. Changing stereotypes, prejudices, and uncertainty in provider–patient relations includes creating interventions to change preconceived ideas of either the patient or the provider that may adversely affect the communication or interaction in the clinical encounter.
6. Requiring public and private health systems to more thoroughly collect and report patient outcomes by race, ethnicity, and primary language. Requiring public and private health systems to more thoroughly collect and report patient outcomes by race, ethnicity, and primary language would improve transparency and accountability around health service inequities and the success of related equity-focused interventions. As research progresses in addressing the complexity of the levels and domains that produce health and health care inequities, such data can help equity interventions become more tailored and effective.

Telegram: @medical_k

www.konkur.in

These six areas for intervention are just some of many potential ways to increase equity in mental health and substance use disorder service outcomes within the lens of the SCF. The overall goal of the SCF is to help stimulate the research and policy thinking that can foster change for health care systems and communities.

56.8 Criminalization of Persons With Serious Mental Illness

Linda E. Weinberger, Ph.D., and H. Richard Lamb, M.D.

The enormously increased presence of persons with serious mental illness in the criminal justice system is one of the great problems of the day. As a result, mental health professionals and society have become much more concerned about the number of persons with mental illness in jails and prisons, as well as the treatment provided to these persons both in such facilities and after release. These issues are relatively recent. Reports of large numbers of persons with mental illness in U.S. jails and prisons began appearing in the 1970s, a phenomenon that had not been reported since the 19th century.

For the purposes of this section, the focus will be on persons with serious mental disorders, that is, schizophrenia, schizoaffective disorder, bipolar disorder, and major depressive disorder. This section discusses the definition of criminalization of such persons and how criminalization came about, the extent of criminalization, the role of the police with regard to persons with mental illness, and the characteristics that are often found in persons with mental illness who have been arrested. The difficulties in treating this population both before incarceration and after release are addressed, including the relationship between serious mental illness and violence and the problems presented by persons who are not able to recognize that they have a major mental illness. The section presents a summation of ways proposed to reduce criminalization. These ways include the following: increased community mental health services that are effective and appropriate to treat persons who are or are at risk of

Telegram: @medical_k

www.konkur.in

becoming criminalized; better coordination among the police, courts, and mental health professionals; mobile crisis teams; increased mental health training for police officers; and diversion programs for offenders with serious mental disorders to prevent them from entering the criminal justice system, as well as transferring those who are already arrested into the mental health system. The necessary components of treatment for such persons will be discussed. These include having clear goals of treatment and practice, establishing a close liaison between treatment staff and the justice system; understanding the need for structure; having a focus on managing violence; and appreciating the crucial role of case management, appropriate living arrangements, and involving family members. Finally, the section ends with a brief discussion of recently enacted criminal justice efforts to decrease the total number of persons incarcerated and recommends possible strategies to reduce the criminalization of persons with serious mental illness.

MAGNITUDE OF THE PROBLEM

The U.S. prison population for both federal and state prisons was 1,430,800 inmates as of December 31, 2019. In addition, at midyear 2019, there were 734,500 inmates held in county and city jails. Although these numbers reflect a small but continuing decline in the rate of incarcerations, the percentage of jail and prison inmates assumed to be seriously mentally ill (schizophrenia, schizoaffective disorder, major depressive disorder, and bipolar disorder) has been estimated at about 16%. Using these numbers yields an estimate of 346,448 incarcerated persons with serious mental illness in jails, and state and federal prisons. Although the actual number may be somewhat higher or lower, depending on the accuracy of the percentage, these figures represent a substantial number.

Moreover, research has shown that approximately one-fourth of persons with serious mental illness in the community have a history of at least one arrest. The association between serious mental illness and arrest is a widespread phenomenon that has affected both the mental health and criminal justice systems.

Telegram: @medical_k

www.konkur.in

Ms. G was a 28-year-old single woman who was diagnosed with schizophrenia at age 22. Prior to her diagnosis, she had a chaotic childhood and adolescence. Her mother abused alcohol and often left her alone in their apartment for days at a time. Ms. G was placed in multiple foster home placements where she frequently eloped, looking for her mother. Attempts at reunification were always unsuccessful due to the mother's continuing neglect and Ms. G's increasing disruptive behavior. At age 18, Ms. G was no longer a ward of the court, and she began living with her 23-year-old boyfriend. She tried to work at fast-food restaurants but found the demands of the job increasingly stressful. She also started to experience paranoid ideas about her coworkers with whom she often fought and heard voices telling her that they wanted to sexually molest her. On one occasion, when she was 20, she fought with her manager and threw his glasses so hard against the wall that they broke. The police were called, and Ms. G was arrested.

During her incarceration, the jail personnel did not recognize that she had a mental illness. She was given probation with no requirement that she obtain psychiatric treatment. She continued to live with her boyfriend until he said she could no longer live with him because of her constant hallucinations and delusions about him. She was now homeless and without money. One day, she walked into a grocery store and stole a loaf of bread and a package of sliced turkey. She was apprehended by a security guard, and the police arrested her. During this incarceration, she was identified as having a mental illness and was treated with antipsychotic medication in jail. Ms. G received probation, but this time was to attend psychiatric outpatient treatment. She went to the community mental health clinic once but did not return because she did not believe she had a mental illness and refused to take any medications.

Shortly thereafter, Ms. G got into a fight with another homeless person and stole his blanket in front of several bystanders who called the police. This led to another arrest where she spent a few months in jail and was again given probation with a condition of outpatient psychiatric treatment. Following her release, she attended outpatient treatment at a mental health clinic for several weeks. Initially, she took her medications which resulted in a dramatic improvement of her symptoms. However, several weeks later, Ms. G stopped taking her

Telegram: @medical_k

www.konkur.in

medications, wherein her symptoms returned, and she became very threatening to the staff. The court was informed of this, and she was remanded to jail. Prior to her release, Ms. G was encouraged to return to her previous outpatient clinic for treatment. Sometime later, Ms. G appeared at the clinic, but the intake team concluded that her history of nonadherence to psychiatric medications along with her past violent behavior could make her a problem in management beyond the capabilities of the clinic.

A few months later, Ms. G was arrested outside a department store for having stolen a sweater and pushing a customer out of her way. This time, she was charged with petty theft with priors and assault, which was a felony. The judge believed he had no option but to send Ms. G to state prison. Criminalization was now confirmed.

Most outpatient mental health treatment facilities are not structured to successfully treat persons like Ms. G, and, as described in this section, community mental health staff is often reluctant to try.

DEFINING CRIMINALIZATION

Many factors come into play in determining why a person with mental illness is arrested rather than taken to a psychiatric hospital.

Generally, persons who are thought to have committed a felony are arrested and brought to jail regardless of their mental condition. The criminal justice system, charged by society with the responsibility for removing from the community persons accused of committing serious crimes, sees no alternative but to first place the person in custody in a secure setting and then arrange for psychiatric treatment, if necessary. If the person is thought to have committed a serious crime, the police and the criminal justice system generally do not want to place this person in a psychiatric hospital because such persons may well pose a number of problematic issues that cannot be treated and managed adequately by the mental health system and thus place society at risk.

Examples of this may be a person with schizophrenia who was found by the police in possession of a loaded gun; he was brandishing the weapon and threatening others because he believed they were poisoning him. Another person with untreated bipolar disorder was arrested after he drove his car erratically on the street and onto a sidewalk full of

Telegram: @medical_k

www.konkur.in

pedestrians because he wanted to be recognized for his race-car-driving skills.

For persons charged with misdemeanors, the situation is more complex. In 1972, the term “criminalization of the mentally ill” was first used. It was observed that persons with mental disorders who engaged in minor crimes were increasingly subject to arrest and prosecution. Later, many authors applied the concept of criminalization to persons with mental disorders who were arrested for serious crimes. The distinction between arrest and incarceration of persons with mental illness who have committed minor offenses and those who have committed serious offenses is an important one.

This section takes the position that the term criminalization should be used primarily in connection to persons with serious mental illness who are arrested and incarcerated for minor offenses instead of being placed in the mental health system. However, it should be acknowledged that many persons with serious mental illness who commit serious crimes and enter the criminal justice system might not have engaged in such behavior if they had been receiving adequate and appropriate mental health treatment at that time.

Concern about the inappropriate placement of persons with serious mental illness in the criminal justice system is not new. As far back as 1939, researchers in Europe advanced the thesis that a relatively stable number of persons are confined in any industrial society. Using prison and mental hospital census data from 18 European countries, they found an inverse relationship between prison and mental hospital populations. They theorized that if one of these forms of confinement is reduced, the other will increase. According to this theory, when prison populations are extensive, mental hospital populations will be small, and vice versa. Thus, if there is room in prisons and a shortage of hospital beds, many persons with mental illness who come to the attention of law enforcement might well be directed to the criminal justice system. Recent research in South America is compatible with this hypothesis. As will be seen in this section, this has happened in the United States and other countries; the census of state hospitals has dropped precipitously while the number of persons incarcerated in the criminal justice system has risen to record proportions.

One of the major concerns in present-day psychiatry is that placement in the criminal justice system poses a number of important problems and obstacles for the treatment and rehabilitation of persons with serious

Telegram: @medical_k

www.konkur.in

mental illness. Even when quality psychiatric care is provided in jails and prisons, the inmate/patient still has been doubly stigmatized as both a person with mental illness and a criminal. Furthermore, jails and prisons have been established to mete out punishment and to protect society; their primary mission and goals are not to provide treatment. The correctional facility's overriding need to maintain order and security, as well as its mandate to implement society's priorities of punishment and social control, greatly restrict the facility's ability to establish a therapeutic milieu and provide all the necessary interventions to treat mental illness successfully. Indeed, such a setting can exacerbate symptoms of mental illness as well as behavior that is noncompliant with the correctional facility's rules; thus, possibly resulting in longer periods of incarceration.

CAUSES OF CRIMINALIZATION

Many factors have been cited as causes for persons with mental illness being placed in the criminal justice system. The most common ones are deinstitutionalization and the unavailability of intermediate and long-term hospitalization in state hospitals for persons with serious mental illness; more formal and rigid criteria for civil commitment; the lack of adequate support systems for persons with serious mental illness in the community, as well as the difficulty such persons coming from the criminal justice system, have in gaining access to community mental health treatment; persons with co-occurring disorders of a serious mental illness and a substance abuse problem being caught up in the war on drugs (being arrested and incarcerated on the basis of the use, sale, and possession of drugs); and a belief by many law enforcement personnel that deviant behavior can be dealt with more quickly and efficiently within the criminal justice system than in the mental health system.

Deinstitutionalization

Beginning in the late 1950s, the inclination to provide hospital beds declined precipitously. This was because of the introduction of psychoactive medications; the development of more efficacious community treatment interventions; the creation of federal programs (e.g., Supplemental Security Income, Social Security Disability Insurance, Medicaid, and Medicare), which would fund community treatment and housing for persons with mental illness; the influence of the civil rights

Telegram: @medical_k

www.konkur.in

movement; and the high cost of institutionalizing persons with mental illness. For example, in 1955, when the number of patients in state hospitals in the United States reached its highest point, 559,000 persons were institutionalized in state mental hospitals out of a total national population of 165 million (339 beds per 100,000 population). By 2016 (as a result of hospital closures and bed eliminations), the number of persons in state mental hospitals dropped to 37,679 for a population of approximately 324,000,000, or 11.7 beds per 100,000 population. This rate is similar to that found in 1850, when persons with serious mental illness received little care and concern. Their plight led to the beginning of the movement, spearheaded by Dorothea Dix and others, to provide more humane care by treating persons with serious mental illness in hospitals. With respect to freestanding and county facilities that provide acute psychiatric inpatient treatment, the number of available beds has also been dwindling. For example, in California, there were approximately 17.16 beds per 100,000 residents in 2017, a loss of more than 42% per capita since 1995.

Deinstitutionalization has thus been viewed as setting the stage for increasing numbers of persons with mental illness entering the criminal justice system. It must be remembered that the community mental health system was developed in the 1960s and 1970s for persons with mental illness who had more moderate needs. Although deinstitutionalization held the promise of persons with serious mental illness being able to live successfully in the community, that hope was not achieved for a sizeable number of individuals. Part of its failure was attributed to a lack of planning before or during deinstitutionalization, as well as a lack of adequate funding. As a result, communities were not able to provide a sufficient community care system (i.e., housing, medical and psychiatric care, social services, and social and vocational rehabilitation) for the formerly hospitalized patients. Despite this, the majority of deinstitutionalized patients were able to adapt successfully in the community; however, this was not the case for a considerable minority who were arrested and placed in jails and prisons or who became homeless (between one-fourth and one-third of homeless persons have a serious mental illness). Some of these individuals presented challenges in treatment—such as not seeing themselves as mentally ill, not taking their medications, abusing substances, and in many cases, becoming violent when stressed. Many of these persons needed highly structured care to

Telegram: @medical_k

www.konkur.in

replace that which had been provided to them, albeit imperfectly, in psychiatric hospitals. The flawed implementation of deinstitutionalization would thus appear to be a significant factor accounting for the migration to jails and prisons of many persons with mental illness who otherwise could have been treated with more adequate services in the community or in a hospital. The criminal justice system had become, by default, a safety net for the mental health system.

Restrictive Civil Commitment Criteria

Many believe that more formal and rigid civil commitment criteria have contributed not only to deinstitutionalization but also to an increased number of persons with mental illness in jails and prisons. In 1969, California's then-novel civil commitment law, the Lanterman–Petris–Short Act, went into effect. Within a decade, every state made similar modifications in their commitment codes. Such a rapid and complete consensus among legislatures is virtually unprecedented. More importantly, it reflected a nearly universal view that past inattention to the rights of persons with mental illness needed to be corrected.

In effect, the new civil commitment laws resulted in three major changes. First, the laws modified the substantive criteria for commitment from more general criteria that simply embodied concepts of mental illness and need for treatment to more specific criteria that embodied either dangerousness to self or others resulting from mental illness or the incapacity to care for oneself. Second, the laws changed the duration of commitment from indefinite and extensive periods to specific and brief periods. Third, the new laws explicitly provided that persons civilly committed have rapid access to the courts, to attorneys, and, in some cases, to jury trials; this access ensured the kinds of due-process guarantees to civilly committed persons that criminal defendants had obtained over the previous decade.

These procedural safeguards and clear commitment standards resulted in fewer, as well as shorter, commitments. Consequently, many individuals with mental illness who otherwise would have been civilly committed by family or others were now left to reside in the community where they might not have been able to care for themselves and control their impulses. Thus, some of these individuals might well have committed criminal acts and entered the criminal justice system.

Telegram: @medical_k

www.konkur.in

Lack of Adequate Community Support Systems

Another factor that both leads to and perpetuates the criminalization of persons with serious mental illness is the lack of adequate support systems in the community. An essential part of support systems for these persons is the availability of community treatment resources. Moreover, the type of community mental health resources available may not be suitable for all of the population to be served.

The availability or lack of availability of treatment resources in the community has three important aspects. First, in most jurisdictions, mental health treatment, housing, and rehabilitation resources are insufficient to serve the very large numbers of persons with serious mental illness in the community. For instance, case management has come to be viewed as one of the essential components of an adequate mental health program. However, the mental health system is ill-prepared to provide quality case management services to all persons with serious mental illness who require it, including those leaving jails and prisons.

Second, community mental health resources may be inappropriate for some of the population to be served. For instance, persons with mental illness may be expected to come to outpatient clinics when the real need for a large proportion of this population is outreach services, in which mental health professionals go to see patients where they live. In addition, some service providers may lack the ability to provide the degree of structure required by many persons with serious mental illness. The issue of structure will be discussed later.

Third, persons with mental illness who have been in jail may not be able to gain access to community treatment even when it is available. Many of these persons have been described as resistant to treatment, dangerous, and seriously substance-abusing, characteristics generally not considered desirable by most community mental health agencies and staff. Furthermore, because many of these agencies may not have the capability to provide the needed structure, limit setting, and security and safety for staff necessary to treat these persons successfully, their reluctance to treat them may be appropriate.

A large proportion of persons with mental illness who commit criminal offenses are found to be highly resistant to psychiatric treatment. They may refuse referral, may not keep appointments, may not be adherent with psychiatric medications, may not abstain from substance abuse, and may refuse appropriate housing placements. There is evidence that many

Telegram: @medical_k

www.konkur.in

of these persons suffer from a disorder called anosognosia (a biologically based inability to recognize that one has a mental illness, and thus a biologically based lack of insight). This is discussed in greater detail later.

Thus, the mental health system finds offenders with mental illness extremely difficult to treat and may be hesitant to serve them. This reluctance may extend to virtually all areas of community-based care, including psychiatric treatment, therapeutic housing, social and vocational rehabilitation, and general social services. Moreover, many offenders with mental illness can be intimidating because of previous violent and fear-inspiring behavior. Treating this group is very different from helping passive, formerly institutionalized patients to adapt quietly to life in the community. Community mental health professionals are not only reluctant but may also be afraid to treat them, especially when measures are not adopted to ensure staff safety. Consequently, these persons are left for the criminal justice system to manage. However, there are outpatient facilities in which structure is provided, security personnel is present, and thus staff is protected, and mental health and criminal justice staff collaborate closely; under such circumstances, many of these persons are successfully treated.

The Role of the Police

The police play an important role in the criminalization of persons with serious mental illness, and this will be discussed in the context of the more in-depth exposition of the police and mental health that follows.

Police and Mental Health. Since the advent of deinstitutionalization and the exodus of persons with mental illness into the community, law enforcement agencies have had an increasingly important function in the management of persons who are experiencing psychiatric crises. The rationale for the police to intervene in the lives of persons with mental illness derives from two common-law principles: the power and the authority of the police to protect the safety and welfare of the community, and the state's paternalistic or *parens patriae* authority, which dictates protection for citizens with disabilities who cannot care for themselves, such as those who are acutely mentally ill.

The police are typically the first responders in the community to urgent situations involving persons with mental illness. They provide services 24 hours a day, 7 days a week. Therefore, they play a major role as a mental

Telegram: @medical_k

www.konkur.in

health resource. They are responsible for either recognizing the need for the treatment of an individual with mental illness and connecting the person with the proper treatment resources or making the determination that the individual has committed a type of illegal act for which the person should be arrested. This responsibility thrusts them into the position of primary gatekeepers who determine whether the individual will enter the mental health or the criminal justice system.

With respect to persons with mental illness, police in all states have the power to transport persons for psychiatric evaluation and treatment when there is probable cause to think that they are a danger to themselves or to others because of their mental condition. As a result, law enforcement officers have assumed the role of "street-corner psychiatrist" by default. Many officers have grown accustomed to this role and consider it one of their duties; however, other officers do so reluctantly, and some do it with resentment. A major problem with having to fulfill this role is that the police have little training in performing this kind of triage. This lack of training is one of the factors that has played an important part in the criminalization of persons with mental illness. The training of law enforcement officers is discussed later in the subsection entitled *Diverting Persons with Mental Illness from the Criminal Justice System.*

The police have a great deal of discretion in the exercise of their duties, including determining what to do when they encounter a person with acute mental illness in the community. In most cases, the police use informal tactics, such as trying to "calm" the person or taking the person home. This practice has been referred to as "psychiatric first aid." In situations that cannot be handled informally, the police may have to take persons with mental illness to hospitals or jails.

In some cases, however, public policy limits the police officer's discretionary power. For instance, if the person with mental illness is alleged to have committed a major crime, the disposition is clear—that person is taken to jail because of the seriousness of the offense.

Often, the interaction between the police and the person with mental illness is initiated by citizens. In such cases, the citizens' demands also may come into play and limit the discretion of the police. For example, many retail stores have a policy that anyone caught shoplifting should go to jail, and store managers are instructed to make a citizen's arrest and call the police without exception. In another kind of situation, people who have just been assaulted by a person with psychosis frequently are not

Telegram: @medical_k

www.konkur.in

inclined to be sympathetic to their assailant, even when a mental disturbance is evident. The result may be an angry citizen insisting that the person be arrested and taken to jail.

Police and Criminalization. As discussed previously, the police play an important role in the criminalization of persons with serious mental illness. Even when the police consider the behavior of a person who has come to their attention to be the result of a mental illness, they may encounter a number of problems and irritants when trying to place the person in an inpatient psychiatric facility. For example, there may be long waiting periods in psychiatric emergency rooms during which police officers cannot attend to other duties. Mental health professionals may question the judgment of the police and refuse admission, or they may admit for only a brief hospital stay a person who just a short time before constituted a clear menace to the community.

However, the police are well aware that if they arrest a person with mental illness, that person will be dealt with in a more systematic and predictable way under the criminal justice system. The individual will be taken into custody; it can be hoped that the person will be seen by a mental health professional attached to the court or in jail and will probably receive psychiatric evaluation and treatment. Thus, an arrest is a response with which police are familiar, one over which they have more control and one that they believe will lead to an appropriate disposition.

Although a person with mental illness suspected of committing a serious crime will most certainly be arrested and transported to jail, a number of factors in addition to those just mentioned have been proposed to explain why a person with serious mental illness suspected of committing a minor offense is arrested rather than taken to a hospital. A person who appears mentally ill to a mental health professional may not appear so to police officers, who, despite their practical experience, have not had sufficient training in dealing with this population and are still laypersons. In addition, mental illness may appear to the police as simply alcohol or drug intoxication, especially if the person with mental illness has been using drugs or alcohol at the time of the interaction with the police. Moreover, in the heat and confusion of an encounter with the police and other citizens, which may include forcibly subduing the person with mental illness, signs of mental illness may go unnoticed. Furthermore, studies have shown that the occurrence of violence at the

Telegram: @medical_k

www.konkur.in

time of a police encounter increases the chances that the person with mental illness will be taken to jail.

Another instance is when law enforcement officers may charge persons with mental illness with a misdemeanor and take them to jail if they think that no other appropriate alternatives are available, a practice that has been referred to as “mercy booking.” Thus, the scarcity of psychiatric inpatient beds and/or limited community mental health services may be a factor contributing to the criminalization of persons with serious mental illness.

MENTAL ILLNESS AND VIOLENCE

In countries that have experienced mass deinstitutionalization since the late 1960s, studies have shown that persons with serious mental illness were more likely to commit criminal offenses and even more likely to commit violent offenses than the general population. This growing body of evidence demonstrates a relationship between mental illness and violence, primarily among persons who do not take their medications and are psychotic. Substance abuse has also been shown to increase the risk of violent behavior, particularly in combination with serious mental illness. Thus, nonadherence to medication, acute psychosis, and substance abuse account for most of the increased violence among persons with serious mental illness. For instance, one study examined persons with serious mental illness in the United States who were arrested over a 10-year period and found that more than one-third were arrested for violent crimes (assault and murder), and more than one-fifth were arrested for drug offenses.

The relationship between serious mental illness and violence is most easily seen in relatively nonviolent societies, such as in Scandinavia. The Scandinavian countries maintain centralized case registries that record comprehensive data on everyone born in the country or who immigrates there. Included in this wealth of data are psychiatric registers and national police registers. In Denmark, the psychiatric registry includes data such as admissions to psychiatric wards, dates of admission and discharge, and discharge diagnoses. There is also a national police register that records all arrests and convictions, as well as information on all criminal proceedings. These registers allow for the computerization and analysis of the data.

Telegram: @medical_k

www.konkur.in

For instance, it was found that males in Denmark with a serious mental disorder who were admitted to a psychiatric hospital by age 44 years represented only 5% of the total population of males but were responsible for about 30% of all the violent offenses committed by males. Likewise, female mental patients in Denmark constituted about 5% of the female population but were responsible for 50% of all the violent offenses committed by females.

In another Danish study, the risk of violent offending was found to be 4.6 times higher for male subjects with schizophrenia and two times higher for those with affective psychoses than for male subjects who were never admitted to a psychiatric ward. For female subjects with schizophrenia, the risk was 23.2 times higher, and for those with affective psychoses, the risk was 3.9 times higher than for female subjects who were never admitted to a psychiatric ward.

Similar findings were noted in Sweden in a study that examined all 15,117 individuals who were born in Stockholm in the same given year. They were evaluated through case registries 30 years later to determine how many were diagnosed with a serious mental illness and were convicted of a violent crime. It was found that 15% of the men and 6% of the women who had a major mental disorder were convicted of a violent offense. A recent study of persons with mental illness in Sweden who were prescribed antipsychotics or mood stabilizers found that violent crime dropped by 45% for those receiving antipsychotics and 24% for those receiving mood stabilizers.

It has been asserted that violent behavior by a subgroup of persons with serious mental illness increases community stigmatization and rejection of persons with mental illness generally. These violent episodes, often highly publicized, may result in the association of mental illness with violence in the public's mind. Such stigmatization can result in the public's reluctance to support funding for adequate mental health services for persons with mental illness. Moreover, there may be less tolerance for integrating persons with mental illness into community housing and finding them appropriate employment. It will be difficult to reduce the stigma of mental illness and its consequences until the violence of this subgroup is addressed. Furthermore, to safeguard the welfare of persons with serious mental illness, as well as the safety of the public, mental health professionals, and society must not ignore the evidence that mental illness is associated with some increased risk of violence.

Telegram: @medical_k

www.konkur.in

Although there is a subgroup of persons with serious mental illness who are violent, it is extremely important to take into consideration data that demonstrate that an even larger group of persons with serious mental illness are the victims of violence. For example, in a review of studies of violent victimization, 35% of persons with serious mental illness were victims of violence within the last year. For persons with serious mental illness, their victimization by violence tends to receive less public attention than the violence that is perpetrated by them.

Anosognosia

Anosognosia is a biologically based inability to recognize that one has a mental illness and thus is a biologically based lack of insight. Researchers have identified various parts of the brain (e.g., ventricles, frontal and temporal lobe subregions, medial temporal and inferior parietal regions, and subcortical structures) where damage is likely to result in anosognosia. Impaired insight may be mediated by deficiencies in conceptual organization and the lack of flexibility in abstract thinking. Generally, lack of insight that one has a serious mental illness is one of the risk factors for violence in persons with schizophrenia, thus demonstrating a relationship between poor insight and violent behavior.

The importance of anosognosia is demonstrated by a study investigating 907 adults who met the criteria for psychotic and affective disorders and received public mental health services. This study found that 26% of these persons with serious mental illness reported being arrested or violent in the last year. These individuals were significantly more likely to deny needing psychiatric treatment.

Overall, these findings suggest that many of the people who are most in need of psychiatric treatment are the least likely to believe that they need it. Treatment nonadherence is a key barrier to implementing evidence-based interventions. Several studies confirm that treatment involvement is related to a lowered risk of arrest and violence in persons with serious mental illness by reducing their psychiatric symptoms and substance abuse. Interventions to improve insight and treatment adherence in this population are warranted and needed.

SOME CHARACTERISTICS OF PERSONS WITH SERIOUS MENTAL ILLNESS WHO ARE

Telegram: @medical_k

www.konkur.in

INCARCERATED

It is known that there are very large numbers of persons with serious mental illness in jails and prisons. What is known about them in terms of their criminal histories and legal status, the psychiatric services they use while incarcerated, and the challenges they might present in psychiatric treatment after release?

Two studies attempted to answer these questions. The first was a retrospective study of inmates with serious mental illness who were arrested and placed in a large, urban county jail. It should be noted at the outset that these findings do not necessarily represent what one would find in a similar study conducted in state and federal prisons or even in other jails. This study revealed that 76% of these inmates required and received psychiatric inpatient care or its equivalent for part of their time in jail during the current offense. Clearly, a large number of people with serious mental illness are receiving their acute psychiatric inpatient treatment in the criminal justice system rather than the mental health system.

With respect to these inmates' history before the current arrest, at least 92% were known to be nonadherent to psychiatric medications, 94% had prior arrests, 72% had prior arrests for violent crimes, and 76% were known to have a history of substance abuse. Given these data, in addition to the fact that three-fourths of these inmates required inpatient psychiatric care in the jail, it would appear that the jail had acquired the responsibility of handling many persons with serious mental illness who were among the most difficult and expensive to treat.

Another study conducted on individuals who had a serious mental illness and were transferred from jail to a psychiatric inpatient unit found that 75% had a history of physical assault in the community, 72% engaged in substance abuse, and 78% were generally nonadherent to medications. Findings revealed that poor insight into illness and nonadherence to medications were associated independently with violence toward others.

That such large percentages of persons in both studies had a history of being nonadherent to psychiatric medications suggests that treatment on re-entry into the community should include such measures as evaluation and supervision by mental health courts, assertive community treatment (ACT), and assisted outpatient treatment (AOT) (see later discussion).

Telegram: @medical_k

www.konkur.in

Moreover, short-term, intermediate-term, or long-term hospitalization may be needed for many.

It was observed in these studies, as it frequently is in jails generally, that a number of persons with serious mental illness are arrested when it appears that their offending conduct was due primarily to their illness. The nature and circumstances of the offense suggest that these persons should have been psychiatrically hospitalized instead of being taken to jail. The following two cases serve to illustrate this point.

A person with psychotic symptoms and a previous diagnosis of Schizophrenia was walking in circles, talking to himself, and then urinating outside a grocery store; he was arrested and charged with indecent exposure. Another person with manic and paranoid symptoms was panhandling at a gas station and yelling that a customer was stealing his money, whereupon he pushed this customer and others. The attendant at the gas station called the police, who arrested him for assault. These individuals would probably have been better served if they were taken to a psychiatric hospital and placed under the jurisdiction of the mental health system rather than being arrested and placed in jail. Incarcerating such persons in settings where it is difficult to provide good treatment, such as jail, does not appear to meet the needs of society by protecting society from dangerous people. Moreover, efforts to reduce the possibility of recidivism by these persons can generally be accomplished by treatment and management within the mental health system.

Using Cognitive Behavioral Therapy to Address Antisocial Characteristics

Some professionals have attributed criminal acts by many persons with serious mental illness primarily to the individual's criminal characteristics. These professionals believe that although there are incarcerated individuals who may have a serious mental illness, many of them are in correctional facilities largely because of their antisocial attitudes and a lack of problem-solving and self-control skills that contribute to their criminal behavior. Consequently, a primary intervention suggested to reduce recidivism is to focus on the antisocial cognitions of these persons.

Indeed, a number of persons with serious mental illness in the criminal justice system may have antisocial tendencies, often to the extent of justifying a diagnosis of antisocial personality disorder. While cognitive-behavioral therapy (CBT) may be a necessary component of the

Telegram: @medical_k

www.konkur.in

treatment regimen for many such offenders in reducing their recidivism, if such persons' thinking and judgment are impaired by their untreated psychotic and manic symptoms, they may not be able to profit from CBT interventions. Therefore, if CBT is to be effective, it should be combined with psychiatric treatment.

Diverting Persons with Mental Illness from the Criminal Justice System

With the very large and increasing number of persons with serious mental illness found in jails and prisons, there have been large-scale efforts to divert them from the criminal justice system to the mental health system. Various stakeholders are involved or affected by diversion: criminal justice personnel, mental health service providers, victims, the arrested individuals' families, and the community-at-large.

Diversion, before the person is actually booked into jail or prebooking diversion, is exemplified by large-scale efforts to create community mobile crisis teams of police officers and/or mental health professionals. In addition, coordination between police and mental health professionals, as well as mental health training for law enforcement officers, may help in reducing arrests

Diversion after booking takes a variety of forms. These include specialized mental health courts, also known as problem-solving courts, that are therapeutically oriented to handle issues related exclusively to offenders with mental illness. Mental health consultation with other courts may also assist the judge by offering recommendations for treatment in lieu of incarceration.

Mobile Crisis Teams. Psychiatric emergencies are managed effectively in communities in which close formal liaisons between law enforcement and mental health agencies are established. These arrangements help to facilitate the resolution of crises of persons with mental illness in the field without the need to resort to hospitalization or incarceration. When resolution in the field is not possible, the existence of these liaisons increases the number of persons with mental illness who are referred to the mental health system rather than jailed, thus reducing criminalization. For those who need psychiatric hospitalization, these relationships tend to increase the rate of acceptance by hospitals.

Telegram: @medical_k

www.konkur.in

Different strategies have been developed to provide a mobile team of police, mental health professionals, or both to respond in the community to persons with mental illness who are in crisis. The following are two of these strategies that are used most commonly.

An increasing number of jurisdictions use sworn police officers who have special and extensive mental health training to provide crisis intervention services as part of crisis intervention teams (CIT programs) and to act as liaisons to the mental health system. This approach is often referred to as the “Memphis Model” because it was developed in Memphis, Tennessee. These specially trained officers may deal with mental health emergency situations on-site or act as consultants to the officers at the scene. This model places a heavy reliance on psychiatric emergency services that have agreed to a no-refusal policy for persons brought to them by the police. Although this strategy has a close liaison with mental health, it does not require the actual participation of mental health professionals in the field.

Another model that some jurisdictions use deploys teams composed of both specially trained sworn police officers and mental health professionals employed by the local community mental health department. These teams have been shown to be effective in resolving emergency situations in the community involving persons with mental illness and in diverting them to the mental health system rather than to the criminal justice system. An advantage of this model is that the mental health professionals on the team may have access to the person’s documented mental health history. Having such data available is an important factor that can help the team better understand the person’s mental condition and make more informed decisions.

The major goals of both of these specialized mobile crisis teams are to resolve the crisis and reduce criminalization. Studies evaluating such teams found arrest rates ranging from 2% to 13% (with an average of less than 7%), in contrast to an arrest rate of 21% for contacts between nonspecialized police officers and persons who were apparently mentally ill. This finding lends credence to the idea that a specialized response lowers the incidence of inappropriate arrests.

Regardless of whether police officers act as part of a team with members of the mental health system in dealing on-site with emergency situations, or police act on their own in dealing with these situations, it is imperative that they obtain all available information about past police

Telegram: @medical_k

www.konkur.in

contacts with the individual when mental illness is thought to be present. Such information may include aspects of the person's actions during previous police contact, such as suicide attempts and violence, and how the previous contact was resolved.

A crucial part of developing and maintaining any specialized mobile response team is that a rigorous and ongoing evaluation of the program must be conducted. For instance, response times—the time from the call to the arrival of the team on the scene—should be measured on a routine basis. If response times are too long, police officers in the field tend not to call on the mobile teams. The teams' arrest rates, and the mental health alternatives they choose, need to be evaluated regularly to be sure that appropriate dispositions are being made and that mental health facilities are cooperating with these efforts.

Increased Coordination and Need for Training. From the standpoint of the police, it is clear that officers need and want rapid on-site assistance from mental health professionals when they are called on to deal with difficult or complex situations involving persons with mental illness who are acutely psychotic, behaving bizarrely, or exhibiting violent behavior, or for persons who have attempted suicide or made a suicide gesture. Similarly, mental health professionals who are working as members of psychiatric emergency teams without police support may feel ill-equipped to handle such individuals in the field. Thus, it has become increasingly apparent in recent years that when persons with mental illness in the community are in crisis, neither the police nor the emergency mental health system alone can serve them effectively and that it is essential for the two systems to work closely together in their planning, implementation, and continuous problem-solving.

Training of Police. Most police departments provide some type of officer training in mental illnesses; however, training in how officers should respond to persons with mental illness who are in crisis is less common. It has been found that when police respond to crisis situations, the risk of injury or death for individuals with serious mental illness is 16 times greater than for those with no serious mental illness. Consequently, mental health training is needed for all police officers, not just for those who are part of the specialized mobile crisis teams. Benefits of training include assisting the police in their interactions with persons who have serious mental illness as well as the potential to reduce injuries.

Telegram: @medical_k

www.konkur.in

Training for police officers about mental health issues and individuals with mental illness should begin in police academies as a regular part of the curriculum. This training should focus on enhancing the understanding of mental illness by law enforcement personnel. Furthermore, it should aim at increasing their knowledge about such mental health issues as how to recognize mental illness, how to handle violence or potential violence among persons with mental illness, what to do when a person is threatening suicide, and when to call the specialized mobile crisis team. In addition, information should be provided as to what mental health resources are available, both inpatient and outpatient, and when a person should be arrested and incarcerated as opposed to being taken to a mental health facility.

For the training to be successful and relevant, trainers should come from both the mental health and criminal justice systems. Trainers from the mental health system should be persons who have experience with crisis intervention in the field and/or in crisis centers, as well as knowledge and field experience relating to the criminal justice system. These mental health professionals must understand and appreciate the challenges and risks that law enforcement officers experience every day in the field. Whereas trainers from the criminal justice system already have credibility with their trainees and knowledge about such issues as officer safety and enforcement protocols that noncriminal justice system persons would not have.

Another important issue to consider when law enforcement officers encounter persons with mental illness is how the individual perceives the officers. Persons with mental illness may have negative attitudes toward the police; they may be fearful of police, believing that the officers do not listen to them, and may use force against them. Such perceptions can lead to dangerous escalating interactions. Consequently, the attitudes and behaviors of both the officer and person with mental illness can influence the outcome of their contact. Understanding how persons with mental illness may perceive law enforcement officers, particularly if they had a previous negative experience with police, is essential.

It needs to be emphasized that mental health training should be an ongoing process, not only for police officers in special mental health crisis teams but also for all police officers.

MENTAL HEALTH SERVICES AFTER ARREST

Telegram: @medical_k

www.konkur.in

To reverse criminalization, it is extremely important to identify persons with mental illness as quickly as possible after they have been arrested and placed in jail. A facility may routinely screen all incoming detainees for serious mental disorders. Initial screenings may be conducted by custody personnel who notice the inmate engaging in odd or bizarre behavior. Medical/psychiatric questionnaires are also used in many correctional institutions as screening devices. Such questionnaires typically consist of less than 20 questions aimed at identifying inmates who may need psychiatric care. Those individuals who endorse items on the questionnaire or who appear to have a mental illness may then be seen by a clinician for a more extensive evaluation to determine what type of housing and/or mental health treatment they should receive while incarcerated. Even more important, if the person is one who should have been treated in the mental health system in the first place, discharge planning should begin as soon as possible after an arrest.

Given the large numbers of persons with serious mental illness who are arrested, jail administrators should be encouraged to negotiate programmatic relationships with mental health agencies to provide multidisciplinary teams of clinicians to work in the jail setting. These teams should include psychiatrists so that psychoactive medications can be prescribed. The teams should be established inside jails to provide short-term crisis intervention, treatment, referral to a psychiatric hospital if necessary, and discharge planning. Such information can be useful in helping the judicial system make decisions concerning the person's legal disposition.

Mental Health Courts

Post-booking diversion strategies are being used increasingly by special courts called mental health courts. The first mental health court that received national attention was established in Broward County, Florida, in 1997, and since then, the number of mental health courts in the United States has increased greatly. Initially, these courts were set up to hear cases of persons with mental illness who were typically charged with misdemeanors. In recent years, these courts have increased their purview to serve persons with mental illness charged with felonies. In mental health courts, all the courtroom personnel (i.e., judge, prosecutor, defense counsel, and other relevant professionals) have experience and training in mental health issues and available community resources. These mental

Telegram: @medical_k

www.konkur.in

health courts have a particular set of characteristics: they hear specialized cases involving defendants with mental illness; they use a nonadversarial team of professionals (e.g., judge, attorneys, and mental health clinician); they are linked to the mental health system that will provide treatment, and they use some form of adherence monitoring that may involve sanctions by the court.

Underlying the concept of mental health courts is the principle of therapeutic jurisprudence, which emphasizes that the law should be used, whenever possible, to promote the mental and physical well-being of the people it affects. The concept of therapeutic jurisprudence operates on the belief that the application of the law can have therapeutic consequences. It should be emphasized that therapeutic jurisprudence does not diminish the importance of public safety, which is fully considered by the court.

In a system characterized by therapeutic jurisprudence, people with serious mental illnesses charged with crimes may be diverted into programs designed to address their treatment and service needs rather than simply being incarcerated with their treatment needs being neglected. Even individuals with serious mental illnesses convicted of serious crimes can be provided with humane and appropriate treatment while incarcerated. Generally, mental health courts facilitate linking offenders with serious mental illness to appropriate needed services and supports on discharge from jail in order to enable them to successfully re-enter their communities.

Mental health courts were developed as a strategy to divert persons with mental illness from the criminal justice system into the mental health system. When offenders with mental illness are booked into jail, their case is usually handled by mental health courts in one of two ways. In the first situation, the prosecution of their cases may be postponed by the judge so that they may be involved in a specified treatment program run by the mental health system.

If they successfully complete the program, their criminal charges are dismissed (or, in some cases expunged), and the individuals are no longer under the jurisdiction of the criminal justice system. If they fail to complete the treatment program successfully, the charges are reinstated, and the criminal proceedings resume. In the second case, the offender with mental illness offers a plea of guilty or *nolo contendre,* which is accepted by the court. The person is sentenced (e.g., sentenced to 180 days in jail,

Telegram: @medical_k

www.konkur.in

which may be held in abeyance) and given probation, which includes treatment by the mental health system as a condition of probation. If the person is nonadherent with treatment or other probationary conditions, probation may be withdrawn, and the sentence imposed. There is evidence that these types of jail diversion may reduce recidivism for persons with serious mental illness.

The mental health court system works in a collaborative effort to devise and implement a treatment plan that includes not only medications and therapy but also housing, social and vocational rehabilitation, income assistance, and family support if possible. These interventions are to address the individual's mental illness and reduce their risk of recidivism. Research has suggested that a factor contributing to reducing recidivism and improving clinical outcomes is when the court and mental health personnel work as a "team" to coordinate and provide services. Clearly, the quality of services plays an influential role in the success of mental health courts. However, there may be unforeseen limitations of these programs with respect to available resources. That is, there are often insufficient community psychiatric treatment, rehabilitation, and housing capabilities in the existing mental health system to accommodate those persons with mental illness who are diverted from the criminal justice system. Another issue that has already been discussed is that many community resources are not appropriate, adequate, or willing to serve a large proportion of those who are diverted from the criminal justice system. Not surprisingly, there is research evidence that this lack of appropriate resources to which diverted persons can be referred results in recidivism.

Another problem resulting from the services recommended by these courts for offenders with mental illness is the possibility that they might be provided at the expense of programs for persons with mental illness who have not committed crimes. When this happens, an undesirable situation may be set up whereby committing a crime offers the patient with mental illness the best chance of getting psychiatric treatment.

These specialized mental health courts have been given high priority because they appear to be part of the answer to the problem of criminalization. However, for these diversionary programs to be truly effective and not overwhelm the already existing limited budgets of the departments of mental health, the treatment to which the courts have referred the offender with mental illness should be funded by additional

Telegram: @medical_k

www.konkur.in

monies. These monies could come, at least in part, from savings in the criminal justice system, which would no longer have to incarcerate and treat these persons.

The Importance of Mental Health Consultation to the Court

Consultative arrangements with mental health professionals may help to correct a problem that involves the computerized criminal histories, or “rap sheets,” available to the court of persons with serious mental illness. Criminal justice personnel, such as prosecutors, probation officers, and parole officers, access the person’s criminal history. It is important to consider what effect this may have on the court’s decision-making regarding the disposition of the individual when there is no mental health input. These computerized criminal histories seldom include a narrative as to what really happened during the previous arrests. Even when a person with serious mental illness commits nonserious offenses, a series of them can result in a lengthy computerized criminal history for the individual. Thus, when such individuals subsequently appear in court, they may look like habitual criminals when their criminal histories are accessed.

By providing mental health evaluation and consultation, it may become clearer in these instances that these are persons with serious mental illness who were not receiving adequate treatment and who repeatedly acted in an inappropriate and/or aggressive manner when stressed, which caused them to come to the attention of law enforcement officers and be arrested. An example would be a woman with a history of bipolar I disorder who has a history of arrests for crimes including disturbing the peace (playing loud music throughout the early morning hours), destroying public property (defacing doors in a county building), resisting arrest for disorderly conduct (screaming at her neighbors in the middle of the night), and hitting a man on the bus whom she falsely believed was making sexual overtures toward her. Her most recent arrest was for throwing rocks at her neighbor because she mistakenly believed he was spying on her while she was taking a shower. Without the input of a mental health professional to evaluate this individual, the judge might believe that she should be incarcerated instead of referred to a hospital or other psychiatric treatment. Thus, this person with serious mental illness would continue to be criminalized.

Telegram: @medical_k

www.konkur.in

OUTPATIENT TREATMENT TO REVERSE OR PREVENT CRIMINALIZATION

To decriminalize persons with serious mental illness, it is necessary to find ways to help them become stabilized outside of jails and prisons and, to the extent possible, not enter the criminal justice system at all. Thus, the community treatment of persons with serious mental illness who are or may become offenders has developed into an increasingly important and urgent issue. There are greatly increased numbers of persons with serious mental illness who find their way into the criminal justice system, are released into the community, and unfortunately, revolve back into the criminal justice system.

A study examined all persons (N = 79,211) who were incarcerated in one state's prison system during a 1-year period. Ten percent were diagnosed as having major depressive disorder, bipolar disorders, schizophrenia, or nonschizophrenic psychotic disorders. Twenty-one percent of these inmates with serious mental illness were currently incarcerated for a violent offense. These inmates also had a statistically higher percentage of assault, robbery, and property offenses than the inmates who had no psychiatric disorder. In addition, inmates with serious mental illness were far more likely to have a history of incarceration than those without a serious mental illness. As a result of this study's findings, the authors acknowledged that there was a need to not only develop programs to treat persons with serious mental illness in correctional facilities but also to find effective alternatives to incarceration in the community, including pre- and postbooking diversion programs, increasing discharge planning or continuity of care programs, drug and alcohol screening and treatment, and access to psychiatric inpatient treatment.

The purpose of this section is to review community treatment of persons with serious mental illness who, without treatment, have been or might become criminalized and to discuss the principles of treating this population as viewed generally by clinicians who conduct such treatment. This includes those who specialize in forensic mental health care. In addition, because such large numbers of persons with serious mental illness have become criminalized and then released into the community, many mental health professionals who previously may not have been involved in treating offenders with mental illness are now finding themselves with treatment responsibilities for this population.

Telegram: @medical_k

www.konkur.in

Probably, many criminalized persons with serious mental illness can be treated at mainstream mental health clinics on their release from jails and prisons. This is exemplified by nondangerous persons with psychosis who are arrested for minor crimes, such as disturbing the peace or not paying for a meal in a restaurant, and who are taken to jail rather than the more appropriate disposition of taking them to a hospital. Another example would be individuals with serious mental illness who committed felonies and were sent to prison but are nondangerous, such as a person with bipolar disorder who was sentenced to prison for forging checks.

However, it must be recognized that there are many who are discharged from correctional institutions who have multiple problems that cannot be adequately treated in traditional community-based facilities. An example of this would be persons with serious mental illness who have a history of dangerousness; placing such persons in a traditional community clinic often results in exacerbations of their illness and acts of violence that lead to rehospitalization or reincarceration. For these individuals, it is important to have special, highly structured clinics staffed by professionals who understand dangerous offenders with mental illness and their treatment. Moreover, adequate security in such clinics is essential; this should include metal detectors, the presence at all times of trained security personnel, and emergency alarm buttons within easy reach of the mental health staff. These clinics may be in the mental health system, with the patients' treatment monitored by the criminal justice system (e.g., court and/or department of probation), or the clinics may be an actual part of the criminal justice system (e.g., run by parole departments).

Treatment of Co-Occurring Disorders

It is estimated by professionals and other personnel in the criminal justice system who are knowledgeable about incarcerated persons with serious mental illness that at least three-fourths of them also meet DSM-5 criteria for Substance Use Disorders. Clearly, if treatment after release is to be successful, both the mental illness and the substance abuse must be addressed. These services should be integrated into the community, and it is generally held that the same clinical personnel should provide and coordinate both mental health and substance abuse treatments. Treatment of co-occurring disorders very frequently needs to be a long-term process.

Telegram: @medical_k

www.konkur.in

Assisted Outpatient Treatment

Another important treatment modality that is available in almost all states is AOT, often called outpatient commitment. AOT is a court-ordered civil commitment in which the patient is not under the jurisdiction of the criminal justice system. Rather, AOT is initiated by the mental health system to ensure that persons with mental illness and a history of hospitalizations or violence participate in services in the community that are appropriate to their needs. AOT is for persons with mental illness who can live in the community with the help of family, friends, and mental health professionals but are resistant to psychiatric treatment, including medications. Without such treatment, they may relapse and become violent and/or dangerous to themselves and require hospitalization. Because of these characteristics, this population is also prone to be arrested, incarcerated, and criminalized. To prevent decompensation, which may result in hospitalization or criminalization, and to help these persons stabilize in the community, such at-risk individuals are ordered to participate in outpatient psychiatric treatment, with their progress closely monitored by the court.

When AOT is successful, it is because there is usually a requirement that it be accompanied by an intensive and proven form of community treatment, such as ACT or forensic assertive community treatment (FACT). ACT is a community-based program with mobile mental health treatment teams that provide an array of treatment, rehabilitation, and housing services that are available 24 hours a day. FACT is similar to ACT but also includes legal leverage via collaboration with the criminal justice agencies in an effort to reduce recidivism. The goal of ACT and FACT is to help persons with serious mental illness stay out of the hospital and develop skills for living in the community. It should be noted that AOT, ACT, and FACT are evidence-based practices; that is, they have been shown to be effective, using scientifically valid studies.

There are many who believe that the widespread use of AOT would reduce the criminalization of persons with serious mental illness because it mandates treatment for individuals who otherwise are likely to be arrested and enter the criminal justice system.

Challenges of Mandatory Outpatient Treatment

Individuals in AOT with serious mental illness, as well as those who have committed criminal offenses, represent a challenge to outpatient

Telegram: @medical_k

www.konkur.in

clinicians. The problem lies not only in ensuring safety of the community but also in working with individuals who may be resistant to treatment.

A large proportion of persons with serious mental illness who commit criminal offenses have a history of being highly resistant to psychiatric treatment before their involvement in the criminal justice system; this is also true for persons who are considered to need AOT. They may have refused referral, may not have kept appointments, may have been nonadherent with psychoactive medications, and may have refused appropriate housing placements. Many have anosognosia and are not able to recognize that they have a mental illness.

For many offenders with mental illness, problems of resistance may continue after release from incarceration, which can place them at risk to the community. This is a fact that the treating professional must always keep in mind.

The mental health system finds many resistant persons with mental illness extremely difficult to treat and is often reluctant or unable to serve them. The reluctance becomes even greater after these persons have committed offenses, become involved in the criminal justice system, and are referred to community agencies. The disinclination to serve these persons extends to virtually all areas of community-based care, including therapeutic housing, social and vocational rehabilitation, and general social services. Many offenders with serious mental illness are intimidating because of previous violent, fear-inspiring behavior. Treating them is very different from helping submissive, nonthreatening, formerly institutionalized patients to adapt quietly to life in the community. Thus, community mental health professionals not only are reluctant but also may be afraid to treat offenders with mental disorders. In addition, professionals may work in treatment facilities that do not adequately provide for staff safety, do not possess the authority and leverage of the criminal justice system, and do not provide treatment interventions with an adequate structure for this population. The reluctance to treat potentially dangerous persons in such treatment facilities may be warranted. Another issue related to mental health professionals' reluctance to treat such individuals is their belief that they do not have adequate training and experience in risk assessment to ensure public safety. As discussed later, outpatient programs need to increase their ability to treat persons who do not see themselves as having a mental illness and/or have a potential for dangerous behavior.

Telegram: @medical_k

www.konkur.in

Another important obstacle to receiving outpatient treatment for persons with serious mental illness who are in AOT or are offenders is that community mental health resources may be inappropriate. For instance, these persons may be expected to come to outpatient clinics when the real need for many in this population is for outreach services where professionals come to them.

As discussed later, a crucial part of the treatment of these persons with serious mental illness is adequately and appropriately structured and supportive therapeutic housing arrangements.

When the Criminal Justice System Is Involved

When the criminal justice system is involved in the outpatient treatment of offenders with serious mental illness, a need exists for a clear understanding of the criminal justice system's perspectives and goals. These perspectives and goals include an emphasis on concerns about public safety, control of violence, extensive use of authority, and close cooperation between the mental health and criminal justice systems.

There are a variety of circumstances under which offenders with mental illness in the community remain under the jurisdiction of the criminal justice system. One such group consists of individuals given probation by the court that includes a condition of outpatient treatment, with the possibility of being sent to jail or prison if they are nonadherent to treatment. Another consists of individuals released from prison who are referred for treatment by their parole officer with the understanding that failure to comply may result in a revocation of parole and return to custody.

Treatment Under the Jurisdiction of the Criminal Justice System

For those offenders who are mandated by the court or an agent of the criminal justice system (probation officer, parole officer) to attend outpatient treatment, the criminal justice system retains jurisdiction over the individual. In such situations, both the offender with mental illness and the therapist must satisfy legal requirements, such as regular attendance and periodic progress reports. The patient must comply with legal restrictions, such as abstinence from drugs and alcohol. Therapists who treat such individuals are often asked to provide reports to the court, probation officer, or parole officer on the patient's treatment, including issues such as attendance, diagnosis, progress, and prognosis.

Telegram: @medical_k

www.konkur.in

Both the criminal justice system and forensic clinicians generally expect that offenders with mental illness given treatment will gain some understanding of the role of their psychiatric disorder in the past and potential future dangerous behavior and that they will avoid behavior or situations that might increase the risk of criminal activity or deterioration in their clinical condition. Moreover, both society and the criminal justice system expect that treatment will be conducted under conditions that can, to the greatest extent possible, ensure safety of the community.

Thus, a balance must exist between individual rights and public safety. However, it has been argued that courts place a greater emphasis on the potential dangerousness of the offender with mental illness than on the individual's rights. In so doing, the courts place the burden on the offender to demonstrate that they no longer pose a danger to the community. Consequently, the person's risk of violence, to a large extent, dictates whether such an individual will be placed into and remain in the community.

Outpatient treatment for offenders with serious mental illness is not designed to make presently dangerous individuals nondangerous. Rather, the criminal justice system presumes that offenders with mental illness placed in outpatient treatment will not be dangerous to others while under supervision and treatment in the community. A primary concern in the outpatient treatment of these individuals is to assess any changes in the mental condition that may indicate violence and to reduce the potential threat of harm. Therefore, features that contribute to a patient's risk of harm are addressed first in treatment. The psychiatrist must assess dangerousness and incorporate this assessment into an intervention strategy. Thus, outpatient clinicians must have as great possible an understanding of each patient's potential for violence as a function of their history and psychiatric condition. Moreover, the clinicians should feel comfortable and qualified to engage in such assessments.

In contrast, in nonforensic psychiatric treatment of nonviolent persons with serious mental illness, the primary focus is usually on alleviation of symptoms. Clinicians who treat offenders with mental illness need to recognize that they have assumed responsibility not only to the patient but also to society in ensuring the patient's safety in the community. This responsibility is not as central when clinicians are treating nonoffenders.

Identifying a Treatment Philosophy

Telegram: @medical_k

www.konkur.in

To work effectively with this extremely difficult group of psychiatric patients, both those in AOT and those who are offenders, the necessity of identifying and articulating a treatment philosophy of both theory and practice should be emphasized. This philosophy, as already mentioned, should strike a balance between individual rights and public safety and use treatment services that take both into account. A reality-based treatment philosophy is needed, one that includes clear treatment goals, with attention paid to goals expressed by the patient; a close liaison with the court or other criminal justice agency monitoring the patient, including access to each patient's database from the criminal justice and mental health systems; and an emphasis on structure and supervision.

The importance of psychotropic medications for this population with a serious mental disorder, most of whom have problems centering on control, cannot be overemphasized. In many cases, if adherence is to be ensured, the patient must live in a community facility in which each dose is dispensed by staff.

A clear conception of the clinical uses and therapeutic value of authority appears to be a cornerstone of successful community treatment for persons with serious mental illness in AOT or for those who are offenders. When treatment is effective, the staff is not ambivalent about the use of authority. They are comfortable about insisting consistently and reasonably that the imposed conditions be followed, monitoring patients' adherence to prescribed psychiatric medications, and monitoring patients to detect the use of alcohol or illegal drugs. They have no problems with insisting that patients live in appropriately structured and supportive residential settings, to the extent needed by each individual, as a condition for remaining in the community. They are willing to rehospitalize patients in community facilities promptly at times of crisis and are willing to recommend revocation of patients' community status and return them to the court with the opinion that community treatment is no longer appropriate.

It is also important to emphasize the legal and ethical aspects of treating persons under the jurisdiction of the court. Before persons in AOT and offenders with mental illness are asked to consent to outpatient treatment, they should be apprised of all the conditions and limitations that will be imposed on them, why they will be imposed, and what will happen if they do not comply. Areas to be addressed include limits to confidentiality, with respect to both past and present treatment and

Telegram: @medical_k

www.konkur.in

criminal history, and conditions under which such information must be shared with criminal justice and mental health system personnel; supervision and monitoring by various authority figures, such as probation or parole officers, judges, therapists, and case managers; mandatory adherence with treatment and other imposed conditions; and residence in an appropriate living situation. The patient must understand that nonadherence to the terms and conditions may result in revocation of outpatient status. It is also imperative that the treatment staff understand the patient's legal status and conditions for community placement fully and agree to monitor and uphold them. Staff members must accept their role as agents of social control.

Treatment Goals

Generally, mental health professionals believe that community treatment of persons with serious mental illness who are in AOT and/or have been offenders should focus on stabilization of the illness, enhancement of independent functioning, and maintenance of internal and external controls that prevent patients from acting violently and committing offenses. It is hoped that patients will share these goals. Patients should at least have the goal of avoiding involvement with the criminal justice system. Important points for discussions between the clinician and the patient are the patient's understanding of which behaviors and symptoms are of concern, why they are of concern, what is expected of the patient both by the clinician and by the supervising court or criminal justice agency, and how the treatment can help the patient to meet these expectations.

Even patients with severe psychiatric symptoms may be able to understand these elements of treatment and adopt appropriate attitudes toward treatment. Thus, a full resolution of symptoms is not always needed for treatment to be viable in a community setting. For some persons with long-term, serious mental illness, total elimination of symptoms is not a realistic goal. Rather, the primary prerequisite for safe and effective community treatment may be patients' ability to understand and accept their clinical needs and the system's legal requirements and to demonstrate adherence.

Liaison Between Treatment Staff and the Court

Telegram: @medical_k

www.konkur.in

Intense supervision and monitored treatment increase successful outcomes. Therefore, an essential aspect of the treatment of offenders with mental illness, especially those under the jurisdiction of the criminal justice system and of persons in AOT, is a close liaison among treatment staff and the court, the district attorney's office, the departments of probation and parole, and the patient's counsel. At the core of the liaison is a complete and relevant database, which is fundamental in understanding the extent of the patient's problems, determining whether outpatient treatment is appropriate for the patient, and developing a treatment plan. The database should include arrest reports, computerized criminal histories ("rap sheets"), hospital records, evaluations by court-appointed psychiatrists or psychologists, results of psychological testing, probation reports, and records from previous hospitalizations, outpatient treatment, and incarcerations.

A successful liaison requires open, frequent, and continuing contact between the treatment staff and the various aforementioned personnel in the legal system. In addition, all must respect each other's perspectives and accept that they are all working toward the same goals. Together, the mental health and legal systems lend their expertise to developing and modifying the most effective community treatment program for patients. Both must accept that such a program cannot be effective for certain individuals who need hospitalization or are too dangerous and thus are not appropriate for outpatient treatment.

The Need for Structure

Usually, patients referred for mandatory outpatient treatment lack internal controls; they need external controls and structure to organize them to cope with life's demands. For instance, mental health professionals who treat this population generally believe that staff should insist that patients' days be structured through meaningful, therapeutic activities such as work, day treatment, and various forms of social therapy. Another basic element of structure for this population is that treatment is mandatory and under the jurisdiction of the court.

What effect does involuntary treatment have on persons with serious mental illness? Adherence has been shown to increase when persons with serious mental illness are required to undergo involuntary treatment. Adherence is important because it has been demonstrated that persons with serious mental illness who do not comply with treatment present an

Telegram: @medical_k

www.konkur.in

increased risk to themselves and to the community. Thus, treatment nonadherence may in and of itself result in rehospitalization or incarceration.

For offenders with mental illness, the criminal justice system tends to view outpatient treatment or conditional release programs as provisional; such programs are not regarded as the right of the offender with mental illness. Thus, the courts are not obliged to grant this form of treatment; if granted, the courts allow the state to quickly and easily revoke it. The possibility of revocation of outpatient status gives the treatment staff powerful leverage to ensure adherence to the treatment conditions.

Finally, it is essential that staff understand and accept the therapeutic value of structure and their use of authority if community treatment of offenders with serious mental illness is to be successful.

Management of Violence

A major focus of therapy should be on high-priority issues, such as the need for the patient to control impulses and inappropriate expressions of anger. Persons whose violence is rooted in a major mental illness often experience their violence as a frightening loss of control. Because their violent acts often occur in the context of psychosis, they tend to perceive a clinician who is not aware of their destructive potential as unable to protect them. They tend to establish that knowledge by testing the clinician for limits. The clinician must be continuously alert and firm in order not to risk being perceived as uncaring and unable to protect the patient from their destructiveness. Treatment contracts made by the psychiatrist and the patient that deal with expectations and consequences openly and from the beginning provide a helpful structure for working with these potentially violent patients.

Persons with serious mental illness, especially those with histories of violent behavior, generally need continuous rather than episodic care. Thus, regular monitoring is needed, especially when symptoms are absent or at a low ebb, in order to deal with individual and situational factors that may arise and result in violence.

Persons with serious mental illness who have been hospitalized or incarcerated frequently enter outpatient treatment while they are still taking medication and may, for the first time in years, find themselves symptom-free, in control of their violent impulses, and able to function in the community. After a while, they may believe that they can succeed

Telegram: @medical_k

www.konkur.in

without medication; they discontinue its use, decompensate, and perhaps engage in violent behavior. Thus, for this population of persons with serious mental illness, many of whom have problems involving control and violence, the importance of continued adherence to antipsychotic medications and medications for bipolar and depressive disorders cannot be overemphasized.

In addition, behavioral, cognitive, and psychoeducational techniques emphasizing anger management have been widely used and are successful in the treatment and management of violence.

Integrating Treatment and Case Management

The purpose of case management is to help patients obtain the services they need in a timely manner and for as long as they need them. Almost all of these patients need the basic elements of case management, which starts with the premise that each patient has a designated professional with overall responsibility for their care.

The case manager formulates an individualized treatment and rehabilitation plan with the patient's participation. As care progresses, the case manager monitors the patient to determine whether they are receiving treatment, have an appropriate living situation, have adequate funds, and have access to vocational rehabilitation. The treatment plan emphasizes helping the patient to deal with practical problems of daily living. In addition, the case manager provides outreach services to the patient wherever they are living, whether alone, with family, in a board-and-care home, or in another residential setting.

Outreach services may take the form of assertive case management. An assertive case management program deals with patients on a frequent and long-term basis. It takes a hands-on approach that may necessitate meeting with patients on "their own turf" or even seeing a patient daily. This form of contact and familiarity with the patient helps the case manager anticipate and prevent significant decompensation. Low caseloads for case managers of potentially violent persons with mental illness—probably not more than ten cases—have been recommended, as have 24-hour-a-day, 7-day-a-week availability. Many violent acts and arrests occur during evenings, nights, and weekends, when traditional treatment programs are closed.

Patients who perceive the case manager as mainly an agent of the court and whose primary intention is to make them "toe the line" will be

Telegram: @medical_k

www.konkur.in

less likely to form a positive relationship with a case manager. They may be guarded and defensive in their interactions. They may also feel a need to portray themselves in a good light, even though they have problems for which they need help. Therefore, case managers, in addition to enforcing the terms and conditions of the court and the treatment, need to be persons who will go beyond this role to secure and provide services and support. It is crucial that patients see the case manager as their advocate to further their treatment and rehabilitation, particularly when agencies in the criminal justice system are dealing simultaneously with them in more coercive or authoritarian ways.

Case managers may experience considerable stress in working with patients in mandatory outpatient treatment. They may feel, with some justification, that they are in danger if they work with persons with serious mental illness who were violent in the past or if their work requires visits to high-crime areas, where many persons with serious mental illness live. Additional problems may include unusual working hours, which may disrupt their family and social relationships, and lack of upward career mobility.

Therapeutic Living Arrangements

Survival in the community for most persons with serious mental illness appears to depend on an appropriately supportive and structured living arrangement. Such an arrangement can often be provided by family members. In many cases, however, the kind and degree of structure the patient needs can be found only in a living arrangement outside of the family home with a high staff–patient ratio, dispensing of medication by staff, enforcement of curfews, and therapeutic activities that structure most of the patient's day.

Some patients need a great deal of structure and supervision in their housing situation. Others need only a minimal amount, and most fall somewhere in between. The treatment staff member assigned to the patient or the patient's case manager must decide whether a particular living arrangement has the appropriate amount of structure to meet the patient's needs. However, it is important to first discuss the suggested living arrangement with the court or the responsible agent in the criminal justice system and obtain their approval.

A consideration for all patients who move from a closed or locked setting such as a hospital, jail, or prison is the patient's ability to handle

Telegram: @medical_k

www.konkur.in

the transition. It is generally not advisable for persons who have been hospitalized or incarcerated for a long time to then be placed in the community in a living situation with little or no structure. Such individuals are frequently unable to cope with the immediate stress and demands of these arrangements, and they either decompensate or commit subsequent offenses.

For many persons with serious mental illness, it is helpful to release them to graduated lower levels of structure—for example, from a hospital or prison to a locked community facility to a halfway house and, when they are ready, to family or independent living. In the graduated release process, close attention must be paid to patients' coping skills and the need for monitoring.

Working With the Family

The role of family members or significant others can be critical in the treatment of offenders with mental illness or for those in AOT. The treatment team should determine whether these individuals were the victims of the patient's aggression, whether they have maintained contact with the patient, and whether they are interested in continuing such contact. The team should also learn whether other social support systems are available while the patient resides in the community. Social support can be an extremely important part of community treatment for persons with mental illness. Assessing problems that may develop between the patient and family members or significant others is essential if contact between them is anticipated.

Another important consideration is the family members' need for guidance and support, especially when they have been victimized by the patient. Clinicians should help them understand the patient's mental condition, teach them to recognize symptoms of decompensation, demonstrate methods for self-protection, and explain the patient's current legal situation.

Moreover, family members should be involved in support groups to help them during crises. In self-help programs, they can benefit from the experience of other families in similar situations.

Diversity, Awareness, and Sensitivity

It is essential that mental health professionals understand how the roles of ethnicity, race, culture, gender, religion, sexual orientation, and age can

Telegram: @medical_k

www.konkur.in

affect one's mental health. Equally important is an understanding of the kinds of treatment and how treatment is presented that will be acceptable to these groups. Only then can the mental health system provide to racial, cultural, religious, and ethnic minorities as well as persons of all ages, sexual orientations, and genders services that are appropriate for their needs and ones to which they will be responsive.

Pitfalls

Mental health professionals must understand their potential liability for the actions of their patients on community status who are prone to violence. They need to be aware that in some states, courts have imposed on therapists a duty of care that extends to the foreseeability of harm. Moreover, the litigious nature of society adds further pressures, stress, and risks. Treating clinicians may be held accountable for patients' suicides, assaults, homicides, and other crimes, even when treatment was mandated, sound, and met the professional community's standards of care. In both public agencies and private practice, malpractice insurance coverage must be adequate so that clinicians feel comfortable, personally and professionally, in undertaking the treatment of persons with serious mental illness who need mandatory outpatient treatment.

Another important concern of those clinicians involved in the community treatment of offenders with serious mental illness, especially persons who have committed high-profile crimes, is the possibility of notoriety and unfavorable publicity. Clinicians may fear that if patients commit further sensational crimes, their professional reputation will suffer, and their facility may receive negative media coverage.

Twenty-Four–Hour Structured Inpatient Care

Not all persons with mental illness can be treated effectively in the community. There is a substantial minority of persons with serious mental illness who need the structure and support of acute, intermediate, or long-term care in a hospital setting or a highly structured, locked 24-hour care community facility. It is important to identify high-risk patients so that scarce community treatment resources are used for those most likely to succeed and for those who are least likely to incur the high costs of lengthy hospitalization or rearrest for serious offenses.

It is essential to facilitate access to hospital care for patients who need it. In the early years of deinstitutionalization, many believed that if the

Telegram: @medical_k

www.konkur.in

counter-therapeutic practices that were exposed in some state psychiatric hospitals could be eliminated, this would simultaneously eliminate the need for hospitals altogether. However, experience has shown that some persons with serious mental illness require hospitalization, and some may need it for an extended period. This may be true even in communities that offer a complete array of excellent and integrated community-based services.

It is important to acknowledge that the community is not necessarily the most benign treatment site for all people with mental illness at all times. Access to hospital care for those who need it for as long as they need it is absolutely essential to the success of deinstitutionalization and the reduction in criminalization for this population.

For those persons with serious mental illness who do not require a setting as highly structured as that of a locked psychiatric hospital but who are not ready for an open community setting, intermediate care facilities have proven extremely valuable. An example is the Institutes for Mental Disease (IMDs) in California. IMDs are locked, private, community intermediate care facilities with a moderate but lesser degree of structure than that found in long-term psychiatric hospitals, such as state hospitals. The facility provides very close medication supervision, with many patients receiving their medication in either liquid or crushed form. The staff–patient ratio is high, with at least 27 hours of activities a week for each patient. These activities include group therapies, therapeutic, social, and recreational activities, and instruction in activities of daily living.

Intermediate care facilities have been used widely for both civil and criminally committed patients. These intermediate care facilities have helped to stabilize persons who might well have been criminalized; for those persons coming from jails and prisons, they might well have prevented recidivism.

Decarceration of Jails and Prisons

Imprisonment rates in the United States increased 500% over the past 40 years, with a peak occurring between 2006 and 2008. Currently, the United States has the highest rate of incarceration in the world. This resulted in prison overcrowding and great financial costs. Consequently, many efforts are underway currently to decrease the number of persons imprisoned. Some of these are reductions in state and federal sentences for less serious crimes, including drug offenses, the use of alternatives to

Telegram: @medical_k

www.konkur.in

prison by means of diversion programs, offering early release to prisoners who participate in rehabilitation programs, and legal mandates to reduce prison overcrowding.

Beginning in 2009, the number of prisoners in U.S. prisons and jails slightly dropped each year. The greatest reduction in prisoners was in California, which exemplifies many of the factors that led to decarceration. In the case of *Brown v. Plata*, the U.S. Supreme Court in 2011 found that overcrowding in California's prisons resulted in a violation of prisoners' constitutional rights and upheld an order to significantly reduce the number of state prisoners. Legislation known as "Public Safety Realignment" was enacted that year which used two primary methods to reduce overcrowding, costs, and recidivism. The first method focused on reducing admissions to prison by having many nonserious, nonsex, and nonviolent felony offenders serve sentences, generally of 3 years or less, in county jail instead of prison. The second method focused on having fewer prisoners return to prison; that is, inmates who previously were released on state parole were now released under county probation to be supervised and provided services by county agencies. If they violated their conditions of probation (but without committing a new crime), they could not be returned to prison but could be placed in jail.

"Realignment" became effective on October 1, 2011. At that time there were 143,710 state prisoners. By May 26, 2021, the number was 92,503, a reduction of 51,207 state prisoners. Persons with serious mental illness may account for a sizeable number of those released. As mentioned previously, recent studies estimate that approximately 16% of persons in prisons have a serious mental illness. If this percentage holds for the 51,207 reduction in state prisoners, then approximately 8,193 (51,207 × 16%) fewer persons with a serious mental illness are incarcerated in California prisons.

In 2018, California added a new statutory scheme (Sec. 1001.35 to 1001.36 Penal Code) to continue reducing the number of persons with mental illness in the criminal justice system by granting pre-trial diversion for individuals with mental disorders. It is not limited to specialty courts, can apply to individuals arrested for misdemeanors and felonies, offers a variety of care settings, and would result in the expungement of the arrest if successfully completed within the 2-year period of diversion. This form of diversion is for defendants whose mental condition played a significant role in the charged offense, who would respond to mental health

Telegram: @medical_k

www.konkur.in

treatment, and who would not pose a significant risk of danger to the public if treated in the community. There are codified exclusionary criteria, including certain serious charged crimes (e.g., murder, rape) and diagnoses (antisocial personality disorder, borderline personality disorder, and pedophilia). States across the nation are addressing the financial costs and effectiveness of incarceration for those currently in prison. Relying on local jails instead of prisons to incarcerate offenders is also likely to result in high costs and overcrowding conditions in the jails and lead to releasing the least dangerous jail inmates for more serious offenders. As a result, arresting persons with serious mental illness who commit or are alleged to commit nonserious, nonsex, and nonviolent crimes and placing them in jails may become less common than in the past.

Consequently, the era of the criminalization of large numbers of persons with serious mental illness may be ebbing in both state prisons and jails. The criminal justice system will not be able to absorb the great numbers that it did formerly. As a result, during decarceration, the mental health system may be expected to assume the care and treatment for far more persons with serious mental illness. Some of these individuals may be among the most difficult and expensive to treat, as well as at great risk of decompensation and/or reoffense. If, however, society gives a high priority to successfully treating and reducing the hundreds of thousands of persons with serious mental illness who are currently in jails and prisons, or who are being released, or who are at risk of being arrested, some similar problems encountered during deinstitutionalization may be avoided.

Some Possible Strategies

The list of problems is formidable, but they can be resolved. There would need to be a very large increase in the number of community mental health services, including ACT and FACT teams and intensive case management; co-occurring disorder programs; administration of antipsychotic medications and mood stabilizers (especially important in reducing arrests for those who have problems involving control and violence); crisis response teams; appropriately structured and supportive housing; vocational rehabilitation; social rehabilitation; availability of acute care in the community; access to acute, intermediate, and long-term inpatient care when needed; more flexible civil commitment laws; and

Telegram: @medical_k

www.konkur.in

AOT when indicated. Many of these interventions are evidence-based practices. With a sufficient amount of all these services being made available, the number of persons with serious mental illness being criminalized should drop significantly.

With the large numbers of persons with serious mental illness who first come to the attention of law enforcement officers, the opportunity to enter the mental health system should be given to those who are appropriate for diversion. Toward this end, there needs to be many more mobile crisis teams, such as CITs of specially trained police officers, who can find alternatives other than arrest and incarceration for such persons in crisis. There should also be increased education and training on mental illness and available mental health resources for law enforcement officers in general. Diversion after arrest may be accomplished in mental health courts (or even general courts), where persons with mental illness are sent to the mental health system to obtain treatment in lieu of incarceration. It needs to be emphasized that pre- and postbooking diversion can be effective only if there are adequate and appropriate mental health resources to which persons with serious mental illness can be diverted.

For those persons with serious mental illness who enter and remain under the jurisdiction of the criminal justice system, creating a successful treatment program for them is a difficult task that demands the input and cooperation of correctional and mental health professionals who are knowledgeable and accepting of the tenets of both the criminal justice system and mental health treatment. A close liaison among such varied professionals helps to maximize a successful outcome for offenders with mental illness. These persons should be provided with appropriate treatment while they are incarcerated and after they have been released into the community. Moreover, all such programs should be evaluated independently to determine which are effective and which are not to ensure the best possible use of scarce resources.

Finally, a significant increase in mental health services, ranging from outpatient treatment and case management to highly structured 24-hour care, would no doubt result in far fewer persons with serious mental illness committing criminal offenses. There is an enormous stigma attached to people who have been in jails and prisons or in a forensic hospital. Such persons have been categorized as both mentally ill and as

Telegram: @medical_k

www.konkur.in

offenders, which makes it extremely difficult to place them in community treatment and housing.

In this time of decarceration, psychiatrists are poised to provide persons with serious mental illness the mental health treatment and supportive social services that were inadequately provided previously for so many and thus led to their decompensation and criminal behavior. If the goals of reducing the criminalization of persons with serious mental illness are to be accomplished, the mental health and criminal justice systems must not only work collaboratively to problem solve but also be provided with all the necessary resources and funding to identify and treat these individuals in the most appropriate setting. It cannot be emphasized enough that the criminal justice system should not be used as a substitute for the mental health system.

57 Psychiatric Education

57.1 Graduate Psychiatric Education

George Alan Keepers, M.D.

Over the last 100 years, the education of physicians in the specialties of medicine has evolved from informal, unsystematized training of variable length and content into the highly regulated residency training programs that constitute the normal educational path for medical school students throughout the United States today. At times gradual, the development of these programs was changed dramatically by the influence of the Flexner report, which resulted in the standardization of both undergraduate and graduate medical education and the adoption of a residency training model begun at Johns Hopkins University. Today, graduate medical education (GME) is undergoing another disruptive episode of evolution championed by the ACGME, the organization responsible for the accreditation of all residency training programs in the United States. In the past, training programs were standardized around the processes and contents of their clinical and didactic curriculum. The Accreditation Council on Graduate Medical Education's (ACGME) competency movement and its more advanced elaboration, the Milestones Project, seek to use measures of the intermediate and final outcomes of residency training to judge the adequacy of training and of training programs.

Telegram: @medical_k

www.konkur.in

This textbook has always covered the subject of psychiatric training, but each author has developed the topic in a somewhat different fashion. In earlier editions, the role of the American Board of Psychiatry and Neurology (ABPN) in influencing training programs was emphasized by Lester Rudy and subsequently by Steven Scheiber. James Eaton, in contrast, emphasized the historical development of the field and the influence of the National Institute of Mental Health (NIMH) in providing funding and direction for the development of high-quality training programs. Most recently, Larry Faulkner reviewed the major organizations that influence psychiatric training programs, provided an overview of the organizational structures that regulate and determine the processes and content of training programs, and addressed issues in psychiatric education that were then relevant.

As Faulkner reviewed in detail, psychiatric educators faced a number of controversial issues in the past. Some of these issues have been resolved, while others continue to be very actively discussed. The interference of service requirements in residency with residents' educational activities has been effectively eliminated by ACGME regulations which limit work hours, require protected time for education and incorporate residents' judgments regarding this issue into the ACGME Psychiatry Residency Review Committee's (PRRC) evaluation of training programs. However, certain new problems have arisen as a result of these regulations. Work compression, which is the pressure to accomplish all patient care activities within a limited time, has created new stressors for residents. Some fear that these pressures result in the loss of adequate training experiences since residents can no longer thoroughly evaluate patients or observe the full course of their illnesses.

Conflict in the training curriculum between biologic psychiatry and psychotherapy education has been reduced by the field's consensus regarding the importance of both and by the specification in the PRRC's Program Requirements (PRs) and residency training milestones (discussed below) of specific training requirements in both areas. The conflict between resident support and resident evaluation has also been softened by recent developments. Academic medical centers are increasingly developing resident support systems that exist outside of departmental structures. The movement toward competency-based education embodied in the milestones supports a developmental rather than summative or judgmental approach to residency training.

Telegram: @medical_k

www.konkur.in

Nonetheless, balancing the provision of specific feedback based on high expectations while maintaining a positive, nurturing environment for residents remains a challenge.

While ABPN certification following residency remains nominally voluntary, two developments in the field have pressured residents and programs toward 100% participation in certification. First, many, if not most, health systems are now requiring American Board of Medical Specialties (ABMS) specialty certification as a condition of credentialing. Second, the PRRC's PRs, which took effect in July of 2019, require that programs maintain an aggregate 3-year pass rate above the bottom fifth percentile of programs in that specialty.

One issue raised in the previous edition remains a significant area of controversy. The limitation of duty hours and reduction in the clinical responsibilities assigned to residents has had the unintended consequence of reducing residents' continuous contact with patients and delaying their maturation as independent practitioners. It is even uncertain as to whether the reductions in work hours have led to the intended improvements in patient safety, perhaps because of the multiplication in transitions of care required in the new paradigm. It is clear that extended shifts of greater than 16 hours have a negative effect on attentional processes and reaction time. But, thus far, studies have not demonstrated increased patient mortality or morbidity from extended resident duty hours. The ACGME and others continue to study this issue.

This chapter adopts a historical approach to the topic of Graduate Psychiatric Education (GPE). The history of psychiatric training will be described, the development of the organizations responsible for regulating it will be reviewed, and the content and structure of residency training as it now exists will be described. Several recent changes in the conduct of GPE will be discussed, and the above and other controversial topics reviewed.

HISTORY OF PSYCHIATRIC EDUCATION

Early History

Prior to Abraham Flexner's 1910 report for the Carnegie Foundation, medical education in the United States was in an abysmal state. There were no established standards for undergraduate medical education, no requirements for GME, and little to no regulation of the practice of

Telegram: @medical_k

www.konkur.in

medicine. Different medical traditions, including allopathy, osteopathy, and naturopathy, provided highly varied training experiences. Physicians might then go directly into practice or seek employment, sometimes under the guidance of a more senior physician who had a particular interest. It was not unusual for physicians to practice in fields for which they had no particular training and for their interests and practice to shift during the course of their careers. Those engaged in what is now called psychiatric practice in the United States fell into two camps—on the one hand, the alienists, and on the other, the physicians who conducted ambulatory practices in nervous conditions. These divisions were not original to the United States but were rooted in developments in the field in Europe. The "spa physicians" made great efforts to assert that their clients and practices were different from the mentally ill. The "alienists" explicitly dealt with severely ill patients and were involved, often as superintendents, with newly developed institutions, frequently state-sponsored, which specialized in the care of severely mentally ill individuals. Originally innovative and providing access to moral treatment, these institutions became so overcrowded that they were at best able to provide custodial care.

Many physicians of varying interests practiced and trained in these settings. For example, Dr. James Hawthorne, who established such an institution in Portland, Oregon, was typical of the physicians of this era. A native of Pennsylvania, he began his study of medicine under the tutelage of a local physician Dr. Bascom, later obtaining a medical degree from the Medical University in Louisville, Kentucky. He opened a general practice in Louisville, which became very successful, and repeated this success in California, starting in 1850. He moved to Portland in 1857, opened a general practice, and subsequently established the Oregon Hospital for the Insane. The Hawthorne hospital eventually had 450 psychiatric beds and was supported on the basis of a contract with the state legislature. It was regarded as one of the finest such institutions in the United States, and Dr. Hawthorne, who had no formal training in psychiatry, was known as an expert in the illnesses of the mind. He was a member of the Association of Medical Superintendents of American Institutions for the Insane (organized in 1844), which became the American Psychiatric Association in 1921. Many physicians practiced at the Hawthorne hospital. Most notably, Simeon Josephi came to the hospital and worked under Dr. Hawthorne's supervision. Dr. Josephi left his employment at the hospital

Telegram: @medical_k

www.konkur.in

to found the Oregon Medical School in 1863. This type of fluid arrangement for training and practice was typical of the times.

Influence of the Flexner Report

Unfortunately, but not surprisingly, this unregulated system led to the public being subjected to poorly trained physicians, naturopaths, and snake oil salesman, all claiming to be legitimate medical practitioners. The American Medical Association (AMA) was organized in 1847 originally to deal with the lack of regulations and standards in medical education and medical practice. Despite the establishment of residency training programs at Johns Hopkins University in 1889, progress was quite limited until the Carnegie Foundation employed Abraham Flexner to study the condition of medical education in the early 1900s. The current system of undergraduate and graduate medical training was founded on Flexner's 1910 report.

Governmental and professional regulatory mechanisms soon followed and have proliferated into a complex group of organizations affecting GPE today. This resulted in the closure of inadequate schools and established allopathy and osteopathy as the only legitimate basis for medical training. Flexner strongly favored the residency program established by Johns Hopkins, and this became and has remained the framework for all residency training in the United States (Table 57.1–1).

Matching Program	activities. Matches residents and programs

Following the Flexner report, several specialties (Ophthalmology, 1916; Otolaryngology, 1924; Obstetrics and Gynecology, 1930; Dermatology and Syphilology, 1932) established boards for the purpose of describing training in the specialty and examining candidates for certification. The ABPN was established in 1934 as a collaborative effort of the APA, the American Neurological Association (ANA), and the AMA. Originally, like other Boards, the ABPN both accredited training programs and certified practitioners.

Establishment of the Accreditation Council on Graduate Medical Education

The burden imposed on the Boards by the accreditation of training programs was substantial, and in 1940 the AMA Council on Medical Education, the American Board of Internal Medicine, and the American College of Physicians established the Conference Committee on Graduate Training in Internal Medicine, a forerunner of the ACGME Residency Review Committees (RRCs). The American College of Surgeons and the American Board of Surgery established their own accreditation bodies in 1949.

Academic educators soon realized that, with the establishment of Medicare and federal funding for residency training, the several accrediting organizations then in existence with widely varying standards for approval of training programs were not tenable and required reform. The case for uniformity of standards with a national scope was supported by the AMA, other medical groups, and the government. In 1972, the AMA sponsored the ABMS, the AHA, the AAMC, and the Council of Medical Specialty Societies (CMSS) to form a Liaison Committee for Graduate Medical Education (LCGME) to coordinate the activities of the independent RRCs then in existence. The failure of this effort indicated that an independent, self-sustaining organization was required to accomplish these tasks, and the ACGME replaced the LCGME in 1981. The ACGME was charged with the responsibility for the accreditation and monitoring of residency programs throughout the United States. In the subsequent years, the current system of RRCs, PRs, and periodic accreditation site visits was developed.

Telegram: @medical_k

www.konkur.in

The evolution of the ACGME PRs in psychiatry has been a collaborative effort between the ACGME, the ACGME PRRC, psychiatric professional organizations, and the ABPN. This has resulted in more uniform, higher-quality training throughout the United States and an alignment between completion of an accredited residency and eligibility to take the ABPN certification examination. Beginning in 2010, the ACGME undertook a major revision of the methods used to evaluate residents and training programs. Entitled the Next Accreditation System (NAS), this new system exchanges yearly reviews of data from all programs with the selection of outliers for review for the old system of in-depth reviews of all programs every 5 years following site visits. The details of this system are discussed below.

The American Board of Psychiatry and Neurology

The ABPN retained the task of certifying graduates of accredited training programs in psychiatry and neurology. The ABPN, like the other 24 specialty boards of the ABMS, is a nongovernmental, independent, nonprofit 501(c) 3 organization governed by a board of directors (Table 57.1–2).

The board is comprised of eight psychiatry directors and eight neurology directors, each of whom serves two 4-year terms (Table 57.1–3). Currently, the Board includes nine neurology directors due to a unique circumstance. Candidates for selection as psychiatry directors are solicited from the APA, the American College of Psychiatry (ACP), and the AMA. The ANA and the American Academy of Neurology (AAN) nominate candidates in neurology. Current directors of the board may also nominate candidates.

Certification methods have changed through the years, and these changes are detailed elsewhere in this text. Two most recent developments are of great importance to psychiatric educators. Ending a 75-year tradition, the last ABPN oral examination in general psychiatry

Telegram: @medical_k

www.konkur.in

was given in Portland, Oregon, at Oregon Health & Science University in 2015. The oral examination in child psychiatry was discontinued not long afterward, with the last examination conducted at Northwestern in Chicago. The new certification examination in General Psychiatry has proven to have very high reliability, with passage rates that are similar to those of the old Part I examination (Table 57.1–4).

2022	1,966	1,752 (89)

Data from American Board of Psychiatry and Neurology (ABPN). Initial Certification Statistics report. Available at: https://www.abpn.org.

Going forward, all of the ABPN's examinations in the core specialties of psychiatry, child psychiatry, and neurology, as well as the subspecialties, will be single certification examinations conducted at testing centers throughout the United States. Psychiatric residency training programs must certify the credentials of their graduates through the computerized ABPN PreCert system as a condition of eligibility to take the examination. Data from this system make it feasible to accurately ascertain the quality of residency training programs as measured by certification examination passage rates for individual programs.

Also of interest is the ABPN's return to a role in the accreditation of residency training programs. The ABPN collaborates with other ABMS boards to develop a number of combined educational programs that are not ACGME accredited. The core programs contributing to the training are ACGME accredited programs, but the training track for residents in the two programs is not. Residents complete training in these programs in less time than it would take to complete the specialty training programs separately. These programs include training that leads to certification in psychiatry and neurology, psychiatry and internal medicine, and psychiatry and family medicine. The Triple Board Program was established as a collaboration between the ABPN and the American Board of Pediatrics (ABP) in 1984. Graduates of these programs may take

Telegram: @medical_k

www.konkur.in

the certification examinations in psychiatry, child and adolescent psychiatry, and pediatrics.

A small but significant number of institutions offer these combined training programs. These programs cannot be accredited by the ACGME, although the specialty programs which participate in them are reviewed and accredited by their respective RRCs. The ABPN has agreed to provide regular review and approval of the combined training programs in order to assure quality training for the residents in these programs and to assure that graduates will be eligible to take the certification examinations in each specialty (Table 57.1–5).

[a]Multispecialty examination.

Modified from American Board of Psychiatry and Neurology (ABPN). ABPN website history. Available at: https://abpn.org/about/mission-and-history/.

The Subspecialties of Psychiatry. Child and Adolescent Psychiatry was the first subspecialty of psychiatry for which the ABPN developed a credentialing process and certification examination. Subsequently, nine other subspecialties were identified, and the ABPN now certifies subspecialists in these areas (Table 57.1–6).

The ABMS has specific criteria for the establishment of new subspecialties, and approval for their inclusion must be obtained from that organization. All of the subspecialties in psychiatry require completion of an ACGME accredited residency, except Brain Injury Medicine, which is still in the grandfathering period extended to 2022, and Addiction Medicine, with a grandfathering period until 2025. The ACGME PRRC accredits Child and Adolescent, Geriatric, Forensic, Consultation-Liaison (changed from Psychosomatics in 2017), and Addiction residencies. The other residencies are administered by other boards. All of the

Telegram: @medical_k

www.konkur.in

subspecialties are 1-year fellowships, except for Child and Adolescent Psychiatry, which is a 2-year program. Residents may enter Child and Adolescent Psychiatry during any part of a General Psychiatry program. One year of training may be counted for both programs, enabling the completion of both programs in 5 years rather than 6. A previous discussion in the field was whether to allow completion or partial completion of the other subspecialty fellowships in the fourth year of the general residency. Although the discussion continues, none of the steps that would be required for such a change have been initiated. All of the subspecialty certifications require taking a single computerized certification examination except for Child and Adolescent Psychiatry. That specialty had traditionally had a Part II oral examination, which was eliminated in 2016 after the completion of the last oral examination at Northwestern in Chicago.

Many subspecialties are developed collaboratively between several ABMS boards. Sleep medicine is an example of such a subspecialty. One of the boards will take the lead in administering the subspecialty and developing the certification examination. Each member board is responsible for credentialing candidates from their own specialty. As new subspecialties are recognized by the ABPN and ABMS, a grandfathering period, usually 5 years, is allowed during which candidates who meet established criteria for experience in the subspecialty area may take the certification examination without completing a residency. After this period expires, candidates must complete appropriate residency training programs to be eligible to take the exam. Of particular recent interest is the development of the multidisciplinary subspecialty of Addiction Medicine, which is administered, oddly, by the American Board of Preventative Medicine. There are now more fellowship programs in Addiction Medicine than in Addiction Psychiatry, and many previously uncertified addiction specialists have taken advantage of the grandfathering period to become certified. The Practice Pathway for such individuals will remain open until 2025.

Modified with permission from Accreditation Council for Graduate Medical Education (ACGME). Data Resource Book Academic Year 2019–2020. Available at: https://www.acgme.org.

The number of core psychiatry subspecialty programs and subspecialty fellows has not kept pace with the increase in the numbers of general programs and residents. Except for Child and Adolescent Psychiatry, these programs have fewer than 90 fellows in training each year. This is problematic from the standpoint of providing an adequate workforce, particularly in geriatric and addiction psychiatry. The failure to interest sufficient numbers of residents in subspecialty fellowship training is the subject of considerable discussion and distress for the profession (Table 57.1–7).

The American Board of Medical Specialties

In 1933, the American Hospital Association (AHA), the Association of American Medical Colleges (AAMC), the Federation of State Medical Boards (FSMB), the AMA, the National Board of Medical Examiners (NBME), and representatives of the four specialty boards in existence at that time (Ophthalmic Examinations, Otolaryngology, Obstetrics and Gynecology, and Dermatology and Syphilology), established the Advisory Board for Medical Specialties. Originally the ABMS was to serve as an advisor to the Boards, a forum for discussion of common problems, and a coordinator of board work when feasible. When expressly delegated by the Boards, the ABMS was to assume control over common policies and procedures. The organization was restructured in 1970 into the ABMS. The AHA, AAMC, FSMB, AMA, and NBME, along with the CMSS, the ACGME, and the Educational Commission for Foreign Medical Graduates

Telegram: @medical_k

www.konkur.in

(ECFMG), continue to serve as associate members of the ABMS. The ABMS derives its funding through levies on the Specialty Boards and, in recent years, has assumed a more directive role with its 24 member Boards. In particular, the ABMS has established standards that the boards are required to follow, specifying what steps diplomats of the boards must take in order to maintain their certification. The ABMS has proposed a revision to these standards that emphasize quality improvement in health care and professionalism. The proposed ABMS requirement that the Boards assess professionalism in their diplomats is controversial for practical and legal reasons.

These Maintenance of Certification (MOC) or Life Long Learning programs currently consist of four elements: professional standing (medical licensure), continuing medical education (CME), self-assessment (SA), and performance in practice (PIP), which includes patient and peer feedback and systematic evaluation of the diplomat's clinical care. Additionally, all diplomats of the boards must document the completion of a patient safety course.

In conjunction with the ACGME, the ABMS and some member boards have begun to offer U.S. training standards for residencies and practitioner certification abroad. Singapore was the first country to request this program and now has a robust program of residency training and certification for several specialties that is similar to the U.S. equivalents. ACGME international programs are now training residents in China, Guatemala, Haiti, Kenya, Lebanon, Oman, Pakistan, Qatar, Saudi Arabia, and the United Arab Emirates, in addition to Singapore. ABMS International has helped to develop certification in examinations in 12 specialties in Singapore, including a certification examination in Psychiatry.

The Liaison Committee on Medical Education

Interestingly, accreditation processes for undergraduate medical education were unified later than the initial wave of certification for specialists. The Liaison Committee on Medical Education was not founded until 1942. Prior to its founding, the AMA's Council on Medical Education and Hospitals inspected and approved medical schools and approved hospitals for internships. The AAMC approved medical schools for membership in the AAMC. Leaders of the AAMC and the AMA, in an effort to avoid duplication of effort, assure the quality of training, protect

Telegram: @medical_k

www.konkur.in

medical students from the wartime draft, and counteract pressures to shorten medical training, established the LCME at a meeting in Chicago. The LCME established and has maintained the standard that made psychiatric education and rotations one of the required experiences for all medical students. This standard has been critical to maintaining an appropriate place for psychiatric education in the medical school curriculum when it has been challenged on intellectual and, more recently, economic grounds.

PSYCHIATRIC EDUCATION TODAY

Resident Recruitment and the NRMP Match

Postgraduate psychiatric education today begins with what everyone calls “the Match.” Prior to the establishment of The National Resident Matching Program (NRMP), enrollment in a residency training program depended on individual negotiations between graduating medical students and the training program’s director. Students were often pressured to accept a position in a program immediately, frequently before they had had an opportunity to interview for and consider other programs. The NRMP was established in 1952 in an effort to prevent these abuses and provide a level playing field for all the programs and applicants. The NRMP is governed by a board of directors, with nominees from the ABMS, the AMA, the AAMC, the AHA, the CMSS, the AAMC Organization of Student Representatives, the American Medical Student Association, the AMA Medical Student Section, and the Consortium of Medical Student Organizations.

Telegram: @medical_k

www.konkur.in

Each year, the recruitment process, in anticipation of the NRMP match day in March, preoccupies most GPE program directors (PDs), senior medical students, and many current residents who are very interested in the younger colleagues who might join them in their residency program. Selecting and recruiting strong candidates for residency training is a critical task for departments. During the recruitment season in 2020 and 2021, all recruitment interviews were done through virtual means due to the COVID pandemic. It remains to be seen whether this methodology will become a permanent feature in future recruitment years. Successful recruitment benefits the department's training program, its future faculty, and the communities which depend on the department for the services of its graduates. Ideal candidates, like those described by Johann Christian Reil in 1803, are the subject of intense competition between training programs.

> Perspicacity, a talent for observation, intelligence, good will, persistence, patience, experience, an imposing physique, and a countenance that commands respect. All those qualities required for the cure of the insane are so rare as to make the staffing of institutions difficult.

It is not much of an exaggeration to say that good residents make good teachers and good training programs. Bright, enthusiastic, conscientious residents are rewarding to teach and contribute to a stimulating scholarly environment. Unfortunately, residents who display the opposite characteristics can cast a pall over the entire training program.

The NRMP has specific guidelines that govern the interview and recruitment process for residency applicants, and all GPE programs and medical students must agree to comply with them in order to participate in the NRMP match. The NRMP has established a uniform date of appointment for GME positions and a system for matching medical students and residency training programs that depends on lists that rank program preference (by the applicants) and applicant preference (by the programs). These lists are computer-matched to produce the best possible outcome for both parties. In 2021, almost 27,000 U.S. medical students (M.D. and D.O.) participated in the NRMP match, and almost 22,000 "independent" applicants applied for approximately 38,000 positions in over 4,000 GME programs across the United States. "Independent" applicants include former graduates of U.S. medical schools, U.S. osteopathic students, Canadian students, and graduates of international medical schools.

Telegram: @medical_k

www.konkur.in

Since 1995, the number of applicants for these positions has substantially exceeded the number of positions. This trend has accelerated over the last 10 years with the inclusion of many more U.S. IMGs and Osteopathic medical students in the Match. This has produced substantial anxiety on the part of today's applicants regarding their likelihood of obtaining a residency position. In fact, the probability of a graduate of a U.S. institution succeeding in the Match has changed little over the last 25 years. About 90% of these graduates will match with a program they have ranked. Other candidates have cause for considerable anxiety. They will succeed in obtaining a position less than 50% of the time. In the last several years, the number of psychiatry training programs and applicants has grown dramatically. Almost all residency training programs in General Psychiatry fill their positions in the match. Recently, many graduates of U.S. medical schools have not been able to obtain a residency position in psychiatry. The proportion of residents from U.S. medical schools is now higher than what is found in Internal Medicine and Family Medicine residency training programs (Tables 57.1–8 and 57.1–9).

Table 57.1–9.
Psychiatry Residency Training Positions, Number of Positions Filled, and Number of Positions Filled by U.S. Graduates 2017–2021

Year	Positions	Positions Filled	Filled by U.S. Graduates
2017	1,495	1,491 (99.7)	923 (61.7)
2018	1,556	1,540 (99.0)	982 (63.1)
2019	1,740	1,720 (98.9)	1,054 (60.6)
2020	1,858	1,838 (98.9)	1,138 (61.2)
2021	1,907	1,904 (99.8)	1,205 (63.2)

Funding of Residency Positions

Telegram: @medical_k

www.konkur.in

The residency positions for which these candidates are competing are funded by a variety of means. The federal government is by far the biggest sponsor of training stipends through two means. First, teaching hospitals receive direct and indirect graduate medical education funding (DME and IME) directly from the Centers for Medicare and Medicaid Services (CMS). These payments are based on a complicated formula that takes into account the percentage of Medicare patients treated at the facility, the historical number of positions when the program was started, and regional cost variations. Many hospitals and universities have many more residents than are approved and funded under the “cap” allowed by this formula, and there are dramatic differences in reimbursement by region. The second mechanism is funds provided by the Veteran’s Administration for residency positions, which in many programs provide a substantial number of stipends. State mental health divisions, community mental health centers, private hospitals, and other organizations also fund some residency positions. All of these organizations expect clinical services in return for the funds they provide. It is often very challenging for a PD to construct a program that satisfies the clinical service demands of the funders and provides the educational program required by the PRs of the ACGME PRRC.

Program Requirements for Psychiatric Training

The ACGME’s process for determining the requirements that programs must meet involves obtaining extensive input from the field, revisions by the RRC followed by more feedback from the field, and subsequent revisions. The ACGME Committee on Requirements reviews the PRs and has the authority to withhold final approval. Increasingly the ACGME has sought to standardize the language and content of the PRs across specialties, so that much of what is found in the psychiatric and psychiatric subspecialty PRs is the same as in other specialties. The PPRs cover the issues of institutional sponsorship and resources, qualifications of the PD and faculty, creation of an academic environment, necessary clinical experiences, mandatory educational curriculum, work conditions, evaluation of residents, evaluation of the program and faculty, and specific outcomes in the language of the ACGME competencies. Recently, the process of evaluating residents has become much more systematic with the development of the milestones (discussed later in this chapter).

Telegram: @medical_k

www.konkur.in

Institutional Requirements. Institutions must make a substantial investment in their residency training programs in order to become ACGME-accredited. Institutional accreditation is required before any residency training program can be approved. The institution must appoint a Designated Institutional Official (DIO) who has authority and responsibility for the oversight and administration of the institution's ACGME accredited programs and is ultimately responsible for compliance with the ACGME Institutional, Common, and Specialty PRs. The institution must also establish a Graduate Medical Education Committee (GMEC), which conducts annual program reviews on all residency training programs and, in general, is responsible for the maintenance of a safe and effective learning environment. Many other aspects of institutional investment are mandated, including sections on resident contracts, work environment, learning environment, and responsiveness to ACGME oversight. The ACGME has recently started a new program of institutional review entitled Clinical Learning Environment Review (CLER). The purpose of this review is to assess the GME learning environment of each sponsoring institution and its participating sites. A site visit is conducted during which the site visitors assess the institution through direct observation and interviews of residents and other personnel. This program duplicates much of the work of the Joint Commission on Hospital Accreditation (JCAHO).

The PPRs further elaborate on what is required to conduct a psychiatric residency training program. The subspecialty PPRs are similar and will not be separately covered. The requirements include special provisions addressing the physical facilities which are necessary for psychiatric training. Adequate office space for interviewing patients and equipment for recording sessions with patients are examples of these types of requirements. The types, length, and supervision of clinical experience specific to psychiatry are detailed in the PPRs, as are certain aspects of the ACGME competencies.

The Program Director. The PPRs specify that the residency training PD must be an ABPN-certified psychiatrist with sufficient administrative and educational experience to take on the challenging task of leading the program. The PD is expected to have full authority over the program and to have sufficient tenure in the position to be effective. The core duties of the PD are mandated in the PRs. These include the selection of training

Telegram: @medical_k

www.konkur.in

sites and the development of program letters of agreement (PLAs) between external sites and the sponsoring institution. The PD must appoint a site coordinator and faculty for each rotation. The PD is responsible for conducting regular evaluations of the rotations and of the faculty and for removing faculty from their teaching roles if necessary. The PD must select residents for the program, evaluate their performance, monitor their stress, and provide twice-yearly formal evaluations. Compliance with ACGME and institutional policies and procedures, particularly those concerning limitations of duty hours and grievance procedures, is required. A summative evaluation at the end of residency training is required, and the resident's rotations and educational experiences must be conveyed to the ABPN at the end of residency to assure eligibility to take the certification examination. The PRRC has, not surprisingly, required that the institution fund and the PD devote at least one-half of their efforts to the training program. Success in this highly technical and demanding position requires at least this much effort.

The Faculty. Psychiatric faculty in an RTP must also be certified by the ABPN, have a strong interest in education, and devote sufficient time to fulfill their supervisory and educational duties. Other teaching physicians should be certified by their specialty board. Non-physician faculty must have completed training, certification, and licensure appropriate to their profession. The maintenance of an academic, scholarly environment is critical to the success of the educational program. All of the faculty should regularly participate in clinical teaching rounds, conferences, grand rounds, journal clubs, and other activities common to the academic setting. Some of the faculty must be engaged in research activities. Demonstration of the faculty's scholarship may be through acquisition of peer-reviewed funding, publication of peer-reviewed articles, other publications, presentations at regional and national meetings, participation in quality assurance activities, and participation and leadership in regional and national professional organizations.

Clinical Experiences. The clinical experiences that psychiatric residents must have during residency are listed in Table 57.1–10. Note that in the first year of residency, the internship must include 4 months of experience in a primary care setting. The purpose and format of the primary care experience are subjects of considerable debate in the field at this time. Currently, most residents complete these experiences in

Telegram: @medical_k

www.konkur.in

inpatient Internal Medicine wards caring for very ill patients for a brief period of time. These clinical situations are unlikely to be encountered regularly in practice by most psychiatrists. They do, however, have a formative effect on the resident's identity as a physician. Experience in ambulatory or integrated care settings may prove to be more valuable to the psychiatrists of the future. Currently, the PPRs do not require training in the collaborative care environments that many psychiatrists and the APA consider essential to the future delivery of psychiatric care.

Table 57.1–10.
Required Psychiatric Graduate Education Clinical Experiences

Experience	Months Required

Community Psychiatry	_[a]
Emergency Psychiatry	_[a]

[a]Required experiences without specific time requirements.
Data from Accreditation Council for Graduate Medical Education (ACGME) Program Requirements for Graduate Education in Psychiatry. Available at: https://www.acgme.org.

Most programs include the required 2 months of experience in neurology in the first year, leaving 6 months which is usually comprised of required psychiatric rotations. Inpatient experiences must include at least 6 months with direct responsibility for the care of acutely ill general psychiatric patients. A wide variety of settings are acceptable for this experience, including traditional inpatient wards, research wards, and

Telegram: @medical_k

www.konkur.in

specialty care units. The outpatient requirement of a year must include longitudinal treatment of patients with multiple modalities. Some of the resident's patients must be seen weekly under supervision for psychotherapeutic treatment. Forensic, emergency, and community psychiatry experiences are not required to have a minimum duration but must include certain key experiences. For example, in their emergency psychiatry experience, residents must evaluate, manage, and triage acutely ill psychiatric patients. Elective opportunities that enhance and specialize residents' training experiences must be available. These are usually provided in the more senior years of the residency (Table 57.1–10).

A unique aspect of the PPRs is the ability to double-count certain experiences for the completion of both the general and child and adolescent residencies. This enables residents to complete training in general and child psychiatry in only 5 years. One month of child neurology, pediatric consultation, addiction psychiatry, and 20% of the resident's ambulatory psychiatry experience may be double-credited, and the experiences in community and forensic psychiatry can count for both programs. This feature, recognized by the ABPN as a legitimate path to eligibility for board certification, has been important to the successful recruitment of residents into child and adolescent training programs.

Didactic Curriculum. A formal didactic curriculum must be provided for the residents during training. The PD is expected to establish goals and objectives for the curricular components that are couched in terms of the ACGME competencies. These have now been considerably elaborated and are covered in the section below entitled Psychiatric Milestones. The curriculum must be designed in a progressive manner that enables resident progression in their knowledge of the field. It is not acceptable to provide the same seminar material to all years of residents simultaneously. The time for the didactics must be protected from clinical duties so that resident attendance is not compromised. The program must document that residents attend at least 70% of these didactic sessions.

Evaluation of Residents. Due to recent radical changes in the process of program evaluation discussed below, the process of resident evaluation in training programs has drastically changed. The ACGME now requires programs to report on each resident's progress twice yearly. A requirement for a Core Competencies Committee (CCC) has been

Telegram: @medical_k

www.konkur.in

established. The PD is expected to appoint the CCC, which must consist of at least three faculty members. Residents may not be members of the CCC. The committee must utilize evaluations provided by clinical supervisors and other personnel on rotations, test scores from the PRITE examination, Clinical Skills Examinations (CSEs), and other evaluative methods. The CCC must rate each resident on the milestones semiannually, and these ratings must be reported to the ACGME. These evaluations are developmental in approach and indicate areas of strength and weakness. The resident, PD, and faculty are expected to work collaboratively to improve resident performance in areas of relative weakness.

Summative evaluations at the end of each residency year and at the end of residency must be recorded so that there is a record of the resident's completion of all required rotations and attainment of sufficient competency on the ACGME competencies to enable independent practice and ethical and professional behavior. Uniquely in psychiatric (and neurologic) training, successful completion of clinical examinations, in which the resident interviews a patient while attaining and maintaining rapport, conducts a mental status examination, and presents the data collected in an organized fashion, is required by the ABPN for eligibility to take the board examination. Psychiatry residents must successfully complete at least three such evaluations during residency. This in-residency oral examination was established by the ABPN as a requirement for eligibility to take the certification examination and is in the PPRs. It replaces Part II of the old board examination. The residency program must provide all of this data to the ABPN through the PreCert system to ensure the eligibility of the resident to take the board examination.

The Psychiatry Milestones

In 1999, the ACGME and ABMS, realizing that medical practice required more than medical knowledge and skill in patient care and procedures, established additional competencies which physicians are expected to attain during the course of their training. These competencies should be regarded as desired outcomes that medical training produces. The six Core Competencies are Patient Care, Medical Knowledge, Practice-Based Learning and Improvement, Interpersonal and Communication Skills, Systems-Based Practice, and Professionalism. Requirements for

Telegram: @medical_k

www.konkur.in

inclusion of training in these areas are included in all of the ACGME PRs and describe behaviors, attributes, or outcomes that must be demonstrated by residents as they advance in training. For example, in the competency of Professionalism: “Residents must demonstrate a commitment to carrying out professional responsibilities and an adherence to ethical principles. Residents are expected to demonstrate: compassion, integrity, and respect for others; responsiveness to patient needs that supersedes self-interest; respect for patient privacy and autonomy; accountability to patients, society and the profession; sensitivity and responsiveness to a diverse patient population, including but not limited to diversity in gender, age, culture, race, religion, disabilities, and sexual orientation; and (specialty-specific outcomes).”

The milestones for residency training represent the next iteration in specifying the outcomes rather than the processes of residency training. Detailed accounts of the development of the ACGME milestones project have been published in the *Journal of Graduate Medical Education* and the *New England Journal of Medicine*. In brief, public and political concern about the outcomes of medical training resulted in a call for reform from the Institute of Medicine (2000), Council on Graduate Medical Education (2007), Josiah Macy Jr. Foundation (2011), and Medicare Payment Advisory Commission (MedPAC) reports (2011). The ACGME response to this crisis in 2008 was to require the creation of milestones describing resident progress in the Core Competencies for all specialties. This project was conceived as a method for evaluation of individual resident progress that would be uniformly applied across the United States and as a method to evaluate the efficacy of residency programs in producing the desired outcomes.

Internal Medicine, Pediatrics, and Surgery were the first specialties to begin milestone development in 2009. In 2011, psychiatry and the other remaining specialties began development with the goal of completing all specialty milestones by 2014. Representatives from the ABPN, APA, American Association of Directors of Psychiatric Residency Training (AADPRT), and ACGME selected individuals to participate in milestone development for psychiatry, and the Working Group and the Advisory Group were formed (Table 57.1–11).

The Working Group was charged with milestone development and began meeting in December of 2011. The Advisory Group reviewed this work and suggested potential improvements. The development of milestones required five meetings and numerous conference calls over the course of the next 2 years. Extensive feedback from the field was sought as part of this process and was incorporated into the final documents. Details of the Psychiatry Milestone development process have been published in Academic Psychiatry. In 2016, the ACGME began the process of revising the milestones due to dissatisfaction with the complexity and inconsistencies in Milestones 1.0. The rationale and processes involved were described in the Journal of Graduate Medical Education. A Milestones 2.0 Group was selected for the revision of the Psychiatry Milestones and developed a set of milestones in which the subcompetencies in System-Based Practice, Problem-Based Learning and Improvement, Professionalism, and Interpersonal Communication

Telegram: @medical_k

www.konkur.in

were more closely aligned with other specialties. Additionally, the Workgroup developed a Supplemental Guide to assist faculty in assessing resident progress (Table 57.1–12).

The milestones are intended to allow faculty to rate the development of a resident's skills, ability, knowledge, attitudes, and behavior in achieving the ACGME competencies during training. They are developmental in nature. Basic skills in an area are expected at the beginning of training. Residents are expected to enhance these skills and, by the end of the residency, attain a level of accomplishment that will allow independent practice. The milestones are organized for the purpose of rating resident accomplishments into five levels. Level 1 corresponds to what is expected of a beginning resident. As residents complete their rotations and educational experiences, they are expected to attain Levels 2 and 3 as intermediate stages of accomplishment. It is important to note that the levels in the milestones do not correspond to PGY levels. Residents will progress at different rates within a program, and programs differ in what experiences they offer residents in each year of residency training. By the

Telegram: @medical_k

www.konkur.in

completion of residency, residents will, on average, have progressed to Level 4 on most milestones. This accomplishment, however, is not sufficient for graduation. The milestones do not measure every quality that is important, and the PD must make an independent judgment on the readiness of the graduating resident for independent practice (Table 57.1–13).

Table 57.1–13.
Description of the ACGME Milestones Levels

Has not achieved Level 1. The resident does not demonstrate the milestones expected of an incoming resident
Level 1. The resident demonstrate milestones expected of an incoming resident
Level 2. The resident is advancing and demonstrates additional milestones but is not yet performing at a mid-residency level
Level 3. The resident continues to advance and demonstrate additional milestones; the resident demonstrates the majority of milestones targeted for residency in this subcompetency.
Level 4. The resident has advanced so that they now substantially demonstrate the milestones targeted for residency. This level is designed as the graduation *target* and does not represent a graduation *requirement.* Making decisions about readiness for graduation is the purview of the residency program director.
Level 5. The resident has advanced beyond performance targets set for residency and is demonstrating “aspirational” goals, which might describe the performance of someone who has been in practice for several years. It is expected that only a few exceptional residents will reach this level.

Accreditation Council for Graduate Medical Education. Data abstracted from discussions in the Psychiatry Milestones Committees.

www.konkur.in

The diagram below presents an example set of milestones for one sub-competency in the same format as the ACGME Report Worksheet. For each reporting period, a resident's performance on the milestones for each sub-competency will be indicated by selecting the level of milestones that best describes that resident's performance in relation to those milestones.

Systems-based Practice 2: System Navigation for Patient Centered Care
A: Coordinates patient care
B: Safely transitions care
C: Appropriately adapts care to meet community needs

Level 1	Level 2	Level 3	Level 4	Level 5
Demonstrates knowledge of care coordination	Coordinates care of patients in routine clinical situations effectively utilizing the roles of the interprofessional teams	Coordinates care of patients in complex clinical situations effectively utilizing the roles of their interprofessional teams	Role models effective coordination of patient-centered care among different disciplines and specialties	Analyzes the process of care coordination and leads in the design and implementation of improvements
Identifies key elements for safe and effective transitions of care and handoffs	Performs safe and effective transitions of care/handoffs in routine clinical situations	Performs safe and effective transitions of care/handoffs in complex clinical situations	Role models and serves as a patient advocate for safe and effective transitions of care/handoffs within and across healthcare delivery systems including outpatient settings	Improves quality of transitions of care within and across healthcare delivery systems to optimize patient outcomes
Demonstrates knowledge of population and community health needs and disparities	Identifies specific population and community health needs and inequities for their local population	Uses local resources effectively to meet the needs of a patient population and community	Participates in changing and adapting practice to provide for the needs of specific populations	Leads innovations and advocates for populations and communities with health care inequities

Comments:

Not Yet Completed Level 1

Selecting a response box in the middle of a level implies that milestones in that level and in lower levels have been substantially demonstrated.

Selecting a response box on the line in between levels indicates that milestones in lower levels have been substantially demonstrated as well as **some** milestones in the higher level(s).

FIGURE 57.1–1. An example of milestones subcompetency performance level reporting. (Reprinted with permission from Psychiatry Milestones, 2nd Revision. © 2020 Accreditation Council for Graduate Medical Education (ACGME). Available at: https://www.acgme.org.)

In the milestones, each of the six ACGME competencies contains subcompetencies that describe specialty-specific elements of the general Core Competency. In the Psychiatry Milestones 2.0, there are 20 subcompetencies. There are an additional 32 subheadings in the milestones, which are called "threads." The Milestones 2.0 revision reduced the number of areas requiring evaluation by 50% (Fig. 57.1–1).

Subcompetencies describe the progression of specific skills, knowledge, or attributes in a single area, such as psychiatric interviewing. The underlying milestones are organized into threads that describe the component skills of the subcompetency and the progression of these skills across the levels (Fig. 57.1–2).

Telegram: @medical_k

www.konkur.in

The psychiatry milestones, subcompetencies, and threads are presented in Table 57.1–14.

Milestones for each of the subspecialties of psychiatry were completed after work on the general psychiatry milestones was finished. This work utilized the experience of the original milestone committee members who participated and chaired the subspecialty development committees to rapidly complete this task. A schematic outline of the subspecialty milestones was created to assist the committees in their task. Committee members met for a single face-to-face working session at the ACGME headquarters in Chicago. The Advisory Committee reviewed the work accomplished at the meeting and provided suggestions. The Working Group subsequently accomplished the revisions through conference calls and online participation. Subspecialty milestones are currently being revised (Table 57.1–15).

The psychiatry milestones represent a major paradigm shift in the overall approach that programs take to resident training and assessment because of their focus on outcomes and their specificity. Because of the process of development, they represent a true consensus of psychiatric educators regarding what residents need to accomplish and what programs need to teach. This shift in emphasis is not, however, without its critics. They have pointed out correctly that there is no evidence that utilization of the milestones will actually produce better psychiatrists. Detractors advocate resident assessment methods that are based on actual patient outcomes. The critics would prefer that there be no change in educational methods until prospective studies establish that there will be a positive outcome. Acceding to such objections would essentially guarantee that postgraduate education remains frozen in its current state. The ACGME has instead adopted a program based on modern quality improvement methods, essentially a PDSA cycle.

www.konkur.in

Version 2 Psychiatry Milestones, ACGME Report Worksheet

Patient Care 1: Psychiatric Evaluation
A: Gathers and organizes findings from the patient interview and mental status examination
B: Gathers and organizes data from collateral sources
C: Screens for risk and integrates risk assessment into the patient evaluation

Level 1	Level 2	Level 3	Level 4	Level 5
Collects general medical and psychiatric history and completes a mental status examination	Efficiently acquires an accurate and relevant history and performs a targeted examination customized to the patient's presentation	Uses hypothesis-driven information gathering to obtain complete, accurate, and relevant history	Elicits and observes subtle and unusual findings	Serves as a role model for gathering subtle and accurate findings from the patient and collateral sources
Collects relevant information from collateral sources	Selects appropriate laboratory and diagnostic tests	Interprets collateral information and test results to determine necessary additional steps	Interprets collateral information and test results to determine necessary additional steps in the evaluation of complex conditions	
Screens for risk of harm to self, to others, or by others	Engages in a basic risk assessment and basic safety planning	Incorporates risk and protective factors into the assessment of imminent, short, and long-term patient safety and the safety of others	Incorporates risk and protective factors into the assessment of complex patient presentations, including eliciting information not readily offered by the patient	Serves as a role model for risk assessment

Assessment of Residency Training Programs

The milestones were not only conceptualized as a method for evaluation of resident progress but are also intended to be used eventually as a method of programs evaluation, and there have been many other changes to the accreditation process.

Incorporation of Osteopathic Training Programs. The ACGME is now responsible for the accreditation of all residency training programs in the United States. In 2014, the American Osteopathic Association (AOA) entered into an agreement with the ACGME to consolidate the accreditation of osteopathic residency training programs under the ACGME. AOA accredited programs could elect to apply for ACGME accreditation until 2020. AOA specialty board certification for faculty in these programs was acceptable to the ACGME during the transition

Telegram: @medical_k

www.konkur.in

period. The programs transitioned to the ACGME may have a co-director certified by AOA specialty boards as long as the other co-director is ABMS-certified. The AOA and AACOM were integrated into the governance structure of the ACGME and are a nominating organization for candidates for membership on the RRCs. All of the RRCs that review AOA programs for accreditation have osteopathic members. By all accounts, this transition has been very successful. AOA programs that applied for ACGME accreditation achieved that status in 98.6% of cases. Graduating DOs success in the NRMP match has increased dramatically, with 99.29% placed either in the Match or through the NRMP's Supplemental Offer and Acceptance Program (SOAP). DOs now serve on the ACGME Board and on 20 of its RRCs (Table 57.1–16).

The Next Accreditation System (NAS). Previously, the ACGME fulfilled its accreditation responsibilities through a system of regular review of programs by the RRC. Data were collected every 5 years for programs in good standing. The PD wrote a Program Information File (PIF), which covered every aspect of program operation in relation to the ACGME PRs. A site visitor would travel to the program and confirm the PIF with interviews with the PD, residents, and faculty. The RRC would then review the data at its meetings, issue an accreditation decision, and issue citations for areas judged out of compliance with the PRs.

The accreditation process has been drastically altered under the NAS. Implemented for seven pilot specialties (emergency medicine, internal medicine, neurologic surgery, pediatrics, diagnostic radiology, and urology) in July of 2013, this system is now being used for all 26 ACGME core specialties. The NAS changes what has been described as a "biopsy" model into a program of annual data collection and review for every training program in the United States. The data sources for this review include an annual resident survey, faculty survey, and data entered by the program into the Accreditation Data Systems (ADS). For many specialties, case logs and board certification pass rates are reviewed annually. It is anticipated that aggregate data from the milestones will be incorporated into the accreditation system after enough experience has been gained.

Table 57.1–14.
Psychiatry Milestones

Telegram: @medical_k

www.konkur.in

Milestone Subcompetencies	Threads
Patient Care 1: Psychiatric Evaluation	A: Gathers and organizes findings from the patient interview and mental status examination B: Gathers and organizes data from collateral sources C: Screens for risk and integrates risk assessment into the patient evaluation
Patient Care 2: Psychiatric Formulation and Differential Diagnosis	A: Organizes and summarizes findings and generates differential diagnosis B: Identifies contributing factors and contextual features and creates a formulation C: Uses the emotional responses of clinician and patient as diagnostic information
Patient Care 3: Treatment Planning and Management	A: Creates treatment plan B: Monitors and revises treatment when indicated C: Incorporates the use of community resources
Patient Care 4: Psychotherapy	A: Establishes therapeutic alliance and manages boundaries B: Selects, sets goals, and provides psychotherapies including supportive, psychodynamic, and cognitive-behavioral C: Manages therapeutic process
Patient Care 5: Somatic Therapies (including Psychopharmacology and Neurostimulation Therapies)	A: Understands the mechanisms of action, indications, and evidence base for somatic therapies and appropriately applies them to patient care

Telegram: @medical_k

www.konkur.in

	B: Educates patients about somatic therapies including access to accurate psychoeducational resources C: Appropriately monitors patient's response to treatment
Patient Care 6: Clinical Consultation	
Medical Knowledge 1: Development through the Life Cycle (including the Impact of Psychopathology on the Trajectory of Development and Development on the Expression of Psychopathology)	A: Knowledge of human development B: Knowledge of pathologic and environmental influences on development
Medical Knowledge 2: Psychopathology (includes Knowledge of Diagnostic Criteria, Epidemiology, Pathophysiology, Course of Illness, Comorbidities, and Differential Diagnosis of Psychiatric Disorders, including Substance Use Disorders and Presentation of Psychiatric Disorders across the Life Cycle and in Diverse Patient Populations)	A: Knowledge to identify and treat psychiatric conditions B: Knowledge at the interface of psychiatry and the rest of medicine
Medical Knowledge 3: Clinical Neuroscience (includes Knowledge of Neurology, Neuropsychiatry, Neurodiagnostic Testing, and Relevant Neuroscience and their Application in Clinical Settings)	A: Neurodiagnostic and neuropsychological testing B: Neuropsychiatric comorbidity C: Application of neuroscientific findings in psychiatry
Medical Knowledge 4: Psychotherapy	A: Fundamentals B: Practice and indications C: Evidence base
Systems-Based Practice 1: Patient	A: Analyzes patient safety events

Telegram: @medical_k

www.konkur.in

Safety and Quality Improvement	B: Appropriately discloses patient safety events C: Participates in quality improvement
Systems-Based Practice 2: System Navigation for Patient-Centered Care	A: Coordinates patient care B: Safely transitions care C: Population and community health needs
Systems-Based Practice 3: Physician Role in Health Care Systems	A: Understanding and working within the health care system B: Health care financing and advocacy C: Transition to practice
Practice-Based Learning and Improvement 1: Evidence-Based and Informed Practice	
Practice-Based Learning and Improvement 2: Reflective Practice and Commitment to Personal Growth	
Professionalism 1: Professional Behavior and Ethical Principles	
Professionalism 2: Accountability/Conscientiousness	
Professionalism 3: Well-Being	
Interpersonal and Communication Skills 1: Patient- and Family-Centered Communication	
Interpersonal and Communication Skills 2: Interprofessional and Team Communication	
Interpersonal and Communication Skills 3: Communication within Health Care Systems

Data from Accreditation Council for Graduate Medical Education. The Psychiatry Milestones.

The data from these sources are statistically analyzed by the ACGME, and outliers are identified for review on the basis of decision rules which are formulated by the RRCs. The data, program history, and previous ACGME actions are then reviewed by ACGME staff for presentation to the RRC. An RRC member conducts a review of the program and presents recommendations at the RRC meeting. The RRC may elect to continue the program's accreditation, continue accreditation with a warning, or ask for a site visit. Programs may be placed on probation following a site visit if problems with the program a very severe. The usual outcome of these

Telegram: @medical_k

www.konkur.in

reviews is to communicate to the program and its sponsoring institution that there are Areas for Improvement (AFIs) or to cite programs for noncompliance with the PPRs. AFIs are issues that may be dealt with by the program and its associated GMEC. Citations require, in addition, communication with the ACGME concerning the program's plan to remedy the problem. Programs with citations are automatically subject to annual review by the RRC.

Data from Accreditation Council for Graduate Medical Education. The Psychiatry Review Committee.

This system has the potential to identify and correct problems in training programs much earlier than the previous accreditation system. Additionally, its developers believe that it will encourage a more rapid pace of program improvement. Criticism of the new system has focused on the increased workload and expense required to comply with the new requirements and on the validity of the data, particularly the resident survey. PDs have expressed concern that residents are often confused by the questions on the resident survey and may answer the questions

Telegram: @medical_k

www.konkur.in

differently when properly oriented. Some studies do indicate that significant differences exist between the results from internal resident surveys and the ACGME resident survey. In 2019, the ACGME undertook the process of revising the resident and faculty surveys in response to these criticisms. A multidisciplinary task force and a commercial firm specializing in survey design completed this task. The revised surveys have been administered, and the results of the revision are being evaluated.

RELATION TO CHANGES IN MEDICAL EDUCATION

These changes in residency training are not occurring in isolation. The traditional system of medical education has been resistant to the incorporation of scientific developments in educational theory and performance improvement that have long been implemented in other educational and corporate settings. Future physicians can expect to be educated quite differently. Medical schools are incorporating the concepts of competency-based education and selecting students who will adapt better to the modern practices of team-based medicine. The requirement that students demonstrate competence at each stage of education is becoming universal. This will require a more flexible approach to the medical school curriculum than currently exists. For example, students matriculate to medical school at varying degrees of readiness. Flexible preparatory curricula are needed to meet varying student needs for additional education prior to their first day of medical school. Ideally, the goal is for every student and every resident to be uniformly excellent—to deserve an A grade. The purpose of competency-based undergraduate and graduate medical education is to raise the level of performance and reduce the variability in educational outcomes.

Following residency education and board certification, it is becoming mandatory that physicians maintain and improve their competence, incorporate new knowledge, and develop new skills throughout their careers. The ABMS and specialty board MOC programs are oriented to this goal. These developments in undergraduate, graduate, and postgraduate medical education are a veritable revolution in the way doctors will be educated. Medical education's past has been one of discrete episodes of learning with little assurance that competence has been attained or will be maintained. Its future is as a lifelong learning

Telegram: @medical_k

www.konkur.in

process with feedback mechanisms ensuring that physicians practice at a uniformly excellent level.

57.2 Examining Professional Patients

M. Sagman Kayatekin, M.D., George Bombel, Ph.D., and Kim-Lan Tran Czelusta, M.D.

Telegram: @medical_k

www.konkur.in

In this chapter, we will talk about the development of a professional during his adulthood. More specifically, this is an attempt to think about human development, with a focus on professional development and how to think about the pauses and regressions in this ever-evolving process—if/when it may go off the tracks during later phases in life due to phase-specific challenges or personal problems like mental illness, substance abuse.

To illustrate the salient points in the professional maturation and growth chart, we will take a psychiatry resident during his residency training and then shift to a professional in their mature adult years, facing various roadblocks. The first section is specific to psychiatric residents. However, much of the discussion would generalize to other professions. Then, in the second section, we broaden our archetypical patient to include other professions.

Despite unique professional development trajectories, we believe that all professionals share expected psychological growth and cognitive development aspects. One crucial common denominator is that professional growth and development occurs in an interpersonal setting. This setting includes not only didactic learning but some form of apprenticeship. This approach is the solid foundation of any profession where there is a need for a supervised training period to develop competent professionals. This is more recognizable for those trained in psychiatry than in sister clinical fields such as medicine, psychology, social work, and nursing. However, it applies to many other fields of human education and professional skills; postgraduate studies in various areas, progression in military ranks or any organization, arts, becoming an artisan, craftsman, or a farmer.

In sum, humans learn and internalize their professional identities as they work, while being embedded in a matrix of a maturationally necessary asymmetric relation with others where information is transmitted through explicit (didactic education, bedside teaching) and implicit ways (identification with teachers as they are performing the tasks they are teaching the student).

PSYCHIATRIC RESIDENCY AS A MODEL OF PROFESSIONAL LEARNING, GROWTH, AND MATURATION

Telegram: @medical_k

www.konkur.in

Starting Residency

Residency training is often the first employee situation for residents since many go directly from high school to college and medical school without a regular and sustained job. Unlike the occasional summer jobs, they may have held, working as a doctor, albeit in training, creates a highly complex nexus of relations, set of rules, regulations, and expectations that the young resident must learn, adapt to, and internalize. Thus, from the end of social role expectancies, these dynamics will reveal many capabilities and fragilities that were relatively dormant due to the person's straightforward, significantly simple interpersonal, and educational life during the "student" years.

It is an interesting dilemma that residents are professionally hybrid persons; although they are employees, they are also learners, which creates a complex web of supervision, milestones, and didactic education. Ultimately, the residency director is responsible for ensuring each resident will competently practice independently and with professionalism. Management of resident difficulties is one of the most time-consuming yet essential responsibilities for a residency director. In addition, the residency director balances complex and often conflicting issues related to fairness to the resident, the program, and the public. As the administrative requirements for residency training continue to increase, having a transparent process in place is essential to support both the residency director and the resident and promote the best outcome possible for all involved.

It is not uncommon for many trainees to have difficulty during these formative years of their professional development during residency. Some difficulties are straightforward and quickly addressed, while others can be extremely challenging, time-consuming, and stressful to all involved. The resident's status as both an employee and a trainee simultaneously guides and complicates addressing problems.

The residency program is poised to make training accommodations to support struggling trainees toward completing residency training. Common modifications include changing rotations or call schedules, increasing supervision, decreasing workload, or repeating a clinical experience. In addition, when approaching a resident's difficulty, the residency director is continually balancing three essential tenets: (1) fairness to the resident, (2) safety to the public, and (3) adherence to program policies to help each resident complete residency training.

Telegram: @medical_k

www.konkur.in

Early Detection of Resident Difficulties

Data sources about resident performance include attending supervisors and chief residents, site-based directors, chiefs of service, on-call faculty, resident peers, administrative staff, patients, nurses, and other hospital staff. Documentation of the concern and subsequent intervention is essential as the concern may be the beginning of a series of later difficulties. In some cases, presenting concerns to the resident and supporting their efforts to reflect on their role in a conflict is a sufficient intervention. This will depend on the residents' openness and responsiveness to feedback.

A resident concern can have multiple contributing factors, and the residency director may not be able to address all etiologies at play. For instance, if the resident concern is a result of family or personal stressors (divorce, sick family member, family conflict), the residency director can offer emotional support in addition to referring to the institution's Psychiatric Counseling Service or Employee Assistance Program. The residency director could also consider temporarily reducing workload or work hours to allow the resident more time to address their situation. However, determining how long such a modified, reduced schedule is reasonable while ensuring the resident meets standard residency training and graduation expectations is not always easy to decipher.

If the resident's difficulty results from problems within the clinical unit or team members, the residency director can help elucidate and address the external factors resulting in residency difficulty. For instance, if the problem stems from a specific staff member of the clinical team with known concerns, then the residency director can provide feedback to the staff member's supervisor, who can then help intervene with the problematic staff member. Interpersonal difficulties with team members sometimes result from the confluence of different interpersonal styles that collide. In such cases, enlisting the help of the responsible attending or chief of the service may be warranted.

Most residents have a predictable developmental course during residency training, but some struggle more than others during the transition from medical student to intern. The increased patient care responsibilities combined with administrative tasks, new electronic medical records systems, teaching expectations, and more advanced specialty-specific clinical skills can be overwhelming and result in difficulties, including time management issues. Moving between large

Telegram: @medical_k

www.konkur.in

urban environments and small towns during medical school to residency training can also be jarring for some trainees. Lastly, leaving a familiar environment with established sources of support to move to a new surrounding with limited early social supports can be isolating.

Fit with the specific residency program may be a factor contributing to a difficult adjustment for residents. Fit encompasses many components and can include geographic location and program size, number of clinical sites and faculty, program culture, patient volume, typical work hours, and call type and frequency. Fit with specialty may be another factor contributing to resident difficulties as it is not uncommon for residents to change specialties in the middle of or after completing training in another specialty.

Finally, a resident's psychopathology or medical illness can play a significant role in resident difficulties. Referral to the institution's Psychiatric Counseling Service, Employee Assistance Program, or community provider offers treatment for the resident and provides information to assist the residency director in determining how to best support the resident. A medical leave of absence may be necessary to allow residents time to address their own health needs. The resident may not successfully meet the demands of residency training and successfully meet graduation requirements depending on the severity of the resident's condition. Residents who have limited insight into their condition or are noncompliant with treatment recommendations can be especially vulnerable to difficulties.

Telegram: @medical_k

www.konkur.in

When problems were noted, Dr. A was a PGY2 psychiatry resident who had excelled academically in her premed studies. She graduated Phi Beta Kappa from college, attended a competitive medical school where she was elected to the Alpha Omega Alpha Honor Medical Society, and then in the first few months, continued to perform at a clinical level that was higher than expected for residents at her level of training. However, her feedback became somewhat uneven in the Clinical Competency Committee meetings over the first 2 years of her residency training. The feedback ranged from “quick thinker, organized, focused, responsible, extreme fund of knowledge” to “challenging, immature, abrasive, poisonous attitude, disrespectful to team. doesn’t see how her actions/words affect others.”

This inconsistent feedback was difficult to convey, and much of it was informal, being relayed verbally to the program director. However, the resident’s written evaluations were average or above average. When her residency director finally provided this feedback, Dr. An attributed the negative comments to mostly jealous and competitive peers and pointed out supervisors’ above-average evaluations. During outpatient rotations of PGY3, Dr. A’s work performance deteriorated further; she was frequently late to clinics and routinely late to close out electronic medical records. Since Dr. A worked at various outpatient clinic settings, the pattern of tardiness was not captured until the end of the PGY3 year.

Despite these various obstacles, the PGY4 year, which mainly was research electives, went relatively smoothly. Dr. A managed to graduate. She was not the stellar student her residency had hoped for but a young clinician with strengths and yet a fragility to develop split relationships. These relationships ranged from positive to negative, depending on the interpersonal context and task; she fared better in environments with a clear frame and comparatively limited close patient or staff contact. Patients’ capacity to activate regressive individual tendencies and evoke split group dynamics with teams was overwhelming for Dr. A. After a process of beneficial psychotherapy and numerous consultations with her director and peers, following graduation, she chose to work in pharmacology research in a major corporation. It was a much less complicated interpersonal context where she could adapt with her introverted sides, and she fared well in this subbranch of her field.

PROFESSIONAL CRISES IN LATER YEARS

Clinical Phenomenology of the Loss of Sense of Self

We will not talk about specific pathologies and their treatment in this chapter—these are described in other chapters. Instead, we will focus on aspects of the clinical presentation and the treatment of "Professionals" that differentiate them from other social groups.

A standard, almost universal theme in the patients we see is the "loss of a sense of self." A lack of sense of self commonly accompanies a major depression or other major Axis I pathology. Nevertheless, some of our professional patients come without any severe pathology but just with a deep, painful sense of loss of self-definition, mainly in the context of a developmental-stage–related challenge.

Almost all of these patients we see have identified very deeply with their professional roles; their professional identity is "the" defining, core aspect of their self-images. Furthermore, this psychically vital element collapses due to exhaustion, common developmental challenges such as promotion or retirement, or major psychopathology.

The roots of this central and psychologically vital professional identification are somewhat complicated. Nevertheless, we describe some of the most common ones in the associated case descriptions.

Identification With Predecessors

Telegram: @medical_k

www.konkur.in

A patient was in his mid-50s and was the heir apparent to a very successful business developed by her father and uncle. She was groomed very early on for this prestigious role, and the patient prepared herself well by attending Ivy League schools, doing a graduate degree in the field, and spending considerable time working on different parts of the organization during any off times from school. However, once she was actually in the leadership role, she had difficulties filling her predecessors' shoes and was constantly being critical of herself and being criticized by the family, hoping she would continue the family heritage. This ongoing discrepancy between the expectation and inability to fulfill it was one central root of her deterioration and hospitalization.

Disidentification

A 40s entrepreneur was from a humble background. His family had lower-class origins where the parents were rather lackadaisical about work, were into using substances, and did not care too much about raising family standards. The patient strongly disidentified with these aspects of his parents and developed a multimillion-dollar company over the years with hard work and luck. However, his only brother had identified with the parents, dropped out of college, and lived a marginal, parasitic life, lost in the world of drugs and multiple unsuccessful short-lived marriages. He committed suicide in his early 40s and following this unexpected horrific loss, around mid-career, the patient crumbled and became a person with no motivation for work, very similar to his brother, before he came to treatment.

Traumatic Abandonment

Telegram: @medical_k

www.konkur.in

A successful doctor in his mid-40 s was hospitalized because of increasing exhaustion over excessive work. He described a sudden paternal loss at the age of early teens/puberty, following which his mother developed severe depression and the patient had to “grow” on his own and very fast; he worked two jobs to make ends meet, took care of his mother and continued his education. It was of note that he could remember little of his relationship with his father, and there was a strong undercurrent of chronic depression/grief that was helped enormously by repressing the painful grief defensively/adaptively in a hypomanic/obsessive way at work. He had accumulated enough wealth to retire by his mid-40s but then crumbled into a depression with a deep sense of “who am I.” He had lost a central, defining element of self that led to a 6-month hospitalization and then ongoing psychoanalytic treatment posthospitalization.

Central Defensive/Adaptive Styles of the Archetypal Professional Patient: the Hypomanic-Obsessive Style

A patient had a background of personal and transgenerational trauma due to immigration from a war zone, parental suicide, and neglect. He described an important adaptive aspect of excessive work quite poignantly; “I wake up with a deep sense of sadness and grief. Then in a matter of an hour, after taking a shower and having my breakfast, I immerse myself in my work, and all these painful feelings disappear. I work excessively and methodically till I exhaust myself and usually others around me. I can maintain my pace on 4 to 5 hours of sleep every day. This cycle repeats itself every morning, and when I can’t work, it becomes intolerably painful.”

Besides the centrality of defining oneself as a professional, we believe in a universal characterologic defensive/adaptive aspect of successful professional patients seen in specialty mental health programs geared toward professionals. This pattern includes the following typical constellation: prominent premorbid hypomanic character traits usually accompanied by obsessive-compulsive personality organizational aspects and a pattern of counter-dependence. For the sake of clinical shorthand,

Telegram: @medical_k

www.konkur.in

we name it as hypomanic-obsessive character organization. The collapse of this structure with defensive and adaptive elements leads to regression and the need for treatment.

The abundance of hypomanic-obsessive presentations in the patient population of our particular Professionals Program provides insights into this relatively neglected style of personality organization. It is as if these hypomanic traits, which allow a broad range of affect to be displayed in a diffusive way, are contained/constrained by obsessive substructures that are the other prominent aspect of personality organization. These patients can work endless days and hours—it is not unusual that a patient takes off only a few days over many years. As one of our patients suggested, “There is something very attractive about working and being successful at it. It is as if work has a way of expanding by itself, intruding into the person’s life once the fulfillments are there”. Moreover, these two elements of their personality structure fit well with their extreme independent/counter-dependent style of relating to others and problem-solving. One patient described this independent cognitive style as having “an internal debate” in decision-making instead of consulting with others.

The literature is abundant for mood disorders, yet hypomanic/hyperthymic presentations are somewhat in the margins of this literature. In addition, there is a debate on whether it is a bipolar spectrum disorder or a temperament. There is evidence that it has genetic connections to creativity. We do know that any illness can be used for defensive and adaptive purposes. Beyond its impact on the human body or psyche, in a person struggling with a chronic or repetitive illness, the person in consideration’s body and mind adapt to this infringement and uses it in an adaptive/defensive manner. Here though, we see some temperamental/learned traits used for defense and adaptation and becoming the central defining element of the patient’s personality.

In common parlance, this is what is coined rather loosely as the concept of “workaholism.” What the typical jargon, of course, misses is the fact that this is not an aspect of the character structure that can be extirpated for treatment, but it is an essential capability of the human mind that can be used more adaptively if it can be brought under the proverbial “domain of the ego.” In an interpersonal level, when operating properly, hypomanic/obsessive style provides the person with extremes of independence, a capacity to make significant decisions on their own without the need for group-think that is more common in successful

Telegram: @medical_k

www.konkur.in

professionals that lead teams of various sizes—from a clinical team to a large organization.

In their detailed life histories, we notice that there are some standard developmental patterns in these patients. Bypassing multiple adolescent developmental tasks is a common element. There is a distorted, stunted, bypassed adolescent growth; a typical pattern is a very early love relationship; they become devoted lovers/friends and join their lives with the person they met in high school or early college years. Thus, they lack a core group of friends; their spouse usually is their "best friend."

Family relationships, time with friends, and other "fun" activities are sorely missing for these patients. Everything they do is tied to an ultimate aim of developing a perfect result—as a professional or parent. They are pervasively result-focused, and, in their worldview, "fun" activities with no purpose are an enigma for them. Paradoxically, they display social anxieties and almost a tendency to schizoid isolation when there is no central work-related task. These core mild schizoid-social phobic aspects are somewhat dormant side by side with impressive capacities to work and be very social within workgroups and lead them to success.

They usually treat their nonwork-related aspects of life with the same principles they successfully utilize in work. Thus, having a final product of a perfect marriage and shining kids becomes a powerful motive. These interpersonal patterns are "counter dependent" in that the patient relates to persons as if they were objects. This approach is very similar to their successful cognitive work modus operandi—they treat job-related issues in meticulous detail with an impressive capacity to make decisions almost singlehandedly—in a fiercely independent intellectual functioning. Similarly, they treat relationships in a nonpersonal distant way and try to fix, find algorithmic solutions, and may even be extremely helpful with their close relationships' decision-making.

Finally, in the background developmental history, quite regularly, there is a history of attachment trauma, parental loss, the transmission of trauma across generations, and unresolved grief, which usually begins around the preadolescent teens.

Clinical Phenomenology of the Decompensation of the Hypomanic-Obsessive Defensive Style

Once regression sets in, three aspects of the presentation stand out: The mood becomes somber, depressed with an agonizing absence of "who

Telegram: @medical_k

www.konkur.in

they are." The obsessive sides shift to a deep incapacitating ambivalence, ambitendence, and ruminations, losing all its impressive analyzing/problem-solving qualities. Finally, the patient develops the presentation of deep sadness, apathy, preoccupation with guilt-ridden ruminations, and extremes of dependence which is the polar opposite of their usual functioning self.

The hypomanic/obsessive style deteriorates to an obsessive/ruminative style and may even lead to precatatonic, and in rare instances, catatonic states.

One of our patients, a 40-year-old businessman, described the progression into catatonia wonderfully. The first sign was a sense of increased anxiety—contextual, concerning conflict within a love relationship, or work-related conflict. Then he recognized a slowing and perseveration of his thought processes and speed. This slowing led to difficulty in building sentences and a general, painful slowing of his psychomotor functioning. Moreover, the crux of the crisis was when he became entirely immobile with thoughts, themes circling in his mind, unable to decide to move around or stay still. He could stay like that for a day. He would be exhausted from keeping a rigid posture and not eating or drinking. As a result, he was hospitalized a few times. Occasionally he would be able to break this agonizing immobile state and pull himself out of the freezing. This syndrome was clearly articulated by earlier clinicians like Kahlbaum and resembled an advanced form of obsessive indecisiveness, ambivalence, and ambitendence.

An example of a milder case is a 70-year-old patient who had fully retired after a successful career. He was observed "stuck" in the doorway to his room on our professional treatment unit. He attempted to go in, took a few steps toward the bedroom, and then walked out of the bedroom a few steps toward the hallway. When we inquired about this, he said he was torn between wanting to go toward and away from his room. He thus repeatedly walked in and out endlessly.

Telegram: @medical_k

www.konkur.in

On a more profound level, the following case exemplifies the tormenting state of ambivalence. The patient, a gentleman in his 60s with a very typical hypomanic/obsessive personality style, was tremendously successful in his line of work. Following retirement, he became depressed. This depression was characterized by the loss of self-definition around his identity as a professional. He decided to come to the hospital after some years of toying with the idea, and it took him about another year-plus to make up his mind after making a final decision to come to the campus. However, it was almost impossible for him to initiate the admissions process once in the building. He could not get in through the doorway of the admissions building. He was stuck. He was begging to be admitted, and a second later, he was telling us that he could not be admitted because he was too sick and needed to be admitted to a locked facility. He then begged that we send him to such a unit as he began lying down and writhing, rolling around on the floor in agonizing anxiety. Finally, after the patient spent a few days in involuntary treatment (that we had initiated), he returned and managed to bring himself to the unit despite a paralyzing sense of indecisiveness and ambivalence.

Once in the unit, he displayed similar symptoms on more subdued and subtler intrapsychic and interpersonal levels. He managed to keep himself in the program but wore down the staff's patience by constantly asking whether he would be transferred again to a locked unit. His indecisiveness was at a level where he would seek guidance on ordinary daily chores, such as on which medications to choose or which foods to eat. Once he got the recommendation on the medication or the food, he would immediately start thinking about the ill effects of the pill or the food he had chosen, become regretful, and try to change his mind again. No ordinary logic counterargument was of any help, and he was aware of this, and this self-awareness made him more ashamed of his behavior. With intense treatment, he slowly cleared from this depressive/obsessive/indecisive pit and maintained a much higher level of functioning in the unit.

For many patients, the painful ruminations flooding their minds when regressing were rooted in beneficial aspects of their cognitive organization when focused and controlled. Premorbid, these patients usually do not

Telegram: @medical_k

www.konkur.in

have an obsessive-compulsive disorder but rather an obsessive-compulsive personality structure. Their meticulousness with details and ability to weigh options were such that they were admired for their analytical skills and their precise decision-making capabilities. However, this solution-oriented cognitive functioning began displaying a “broken record” quality when decompensated, and there was no processing but futile repetition of similar themes. So, the crumbling of the hypomanic-obsessive defensive/adaptive structure and the accompanying loss of sense of a central definition of self would add to the patient’s problems and worsen the patient’s depression.

TREATMENT: UNFOLDING INTO THE SYSTEM, REPEATING THE STORIES OF THEIR LIVES

This chapter will focus on some unique aspects of the treatment specific to this clinical population. However, standard treatments, such as psychopharmacologic agents, should be used when appropriate. Also, sleep problems are pervasive and can be treated with cognitive-behavioral therapy for insomnia (CBTi) or appropriate medications. For older professionals, cognitive evaluations are essential. In our experience, it is rare not to treat patients with some standard psychiatric treatment.

Our repeated experience is that psychotherapeutic approaches and biologic treatments work on similar neural substrates and, if appropriately combined, tend to potentiate one another. In the last few decades, the worldwide increase in moving away from monolithic and exclusionary/antagonistic “biologic” versus “psychological” theories toward more integrative theories of mind and mental illness is a witness to this fundamental, paradigmatic shift.

Some Central Therapeutic Elements of This Unique Setting

Repetition is one primary key—one way to evaluate these patients’ intrapsychic/interpersonal scripts is how they unfold into professionals’ programs and repeat their central issues: conflicts, deficits, interpersonal modii of operandi. A central dynamic is the externalization of internal representational scripts in the form of; seeing the self in staff and peers, seeing the object in staff and peers, group dynamics that unfold with peers, and transferences to hospital. Enactments and clearing from enactments are central to treatment.

Telegram: @medical_k

www.konkur.in

Due to the therapeutically regressive elements (limited time, relative confinement to a physical space with other peers, intense group dynamics, regressive pulls of therapies), there is rapid individual/group regression, and the patient presents intrapsychic and interpersonal functioning with relative transparency in the milieu.

The psychotherapeutic hospital is an environment where the patient constantly tests functional beliefs, distortions, and expectations. As a result, various transference, countertransference, and enactment scenarios develop and are lived through and interpreted.

Patients report that it is much easier to open up and talk about their experiences honestly in the hospital setting because they feel a sense of belonging when they hear the stories of fellow patients—the pathologically grandiose fantasy that they are alone, the only one with this kind of embarrassing mental health problem dissipates very rapidly. It becomes a more ordinary and shared experience.

As well-established research demonstrates, psychotherapeutic hospitals, which offer more extended immersion into various psychotherapy and biologic therapies, are conduits of impressive and promising change. However, in essence, we probably still do not have a refined, satisfactory theory of how these unique human ecologies work.

As a demonstration of an approach to treat professional patients, the remainder of this chapter will describe a representative case in detail.

Treatment Example: Marvin

Telegram: @medical_k

www.konkur.in

Marvin was a divorced, 60-year-old and CFO of a technology company with a vague history of anxiety, dysphoria, perfectionism, and aloofness. From his perspective, he was primarily content and healthy aside from intermittent "blue spells" over the years. These spells were quickly ameliorated with medication changes; however, 6 months before the current series of inpatient psychiatric treatments, he decided to "preretire" to escape a painful work situation and spend more time with his wife, two adult children, and several grandchildren. This retirement involved stepping down from CFO to a part-time consultant to the company's board, a move that immediately left him feeling empty, directionless, worthless, and psychologically collapsed. In turn, he became overwhelmed with regret and severe rumination about the decision to preretire. Dread, anxiety, and dysphoria overtook him, and he became suicidal—eventually culminating in suicide attempts. After the most recent (benzodiazepine overdose), he was admitted to a crisis-stabilization unit in his city, then transferred to a partial hospital program.

PSYCHOLOGICAL ASSESSMENT. As a part of a thorough evaluation, Marvin's treatment team requested a psychological assessment to clarify stressors, defenses, interpersonal relations, thought processes, coping capacities, and diagnosis, and to receive treatment recommendations. Marvin participated in a clinical interview, then completed the Millon Clinical Multiaxial Inventory—4th Edition (MCMI-IV), the Thematic Apperception Test (TAT), and the Rorschach Inkblot Test, using the Rorschach Performance Assessment System (R-PAS) administration and scoring guidelines. During the assessment sessions, Marvin presented with a fragile but determined grin that was insufficient to mask his underlying dysphoria. His thought process was ruminative, focusing on the loss of his CFO role, and recent marital conflicts. Nevertheless, he remained tense, polite, cooperative, and engaged throughout the process, though mildly condescending at times and doubtful that the assessment would provide any new insights about how his mind works.

The assessment data suggested that, behind his defensive functioning, Marvin felt fundamentally inadequate, broadly ineffective, emotionally weak, and flawed in significant ways. For example, despite his successes, he described feeling socially inept and awkward in most life spheres (with

Telegram: @medical_k

www.konkur.in

friends, family, colleagues). Concomitantly, he tended to suspect that others are ever-poised to hurt, criticize, reject, shame, humiliate, or deceive him—so he was pretty suspicious, though he did not appear to reach the threshold for clinical paranoia. These perceptions of self and others left him shy, apprehensive, and racked with self-doubt. Marvin's primary strategy for managing this pain, uncertainty, and fear was an avoidance pervasive and robust enough to resemble schizoid withdrawal. Thus, on the surface, he appeared distant, aloof, emotionally detached, or even indifferent to others—and although willing to engage in some obligatory family and business engagements, he appeared to prefer solitary activities. However, this presentation was more reflective of assiduous efforts to deny longings for closeness and approval to neutralize the internal conflict, for example, if he had no desire, he did not need attachments and therefore could not truly be hurt. Broadly, in concert with natural human longings for social contact and acceptance, Marvin's insecurities oriented him toward others (e.g., for soothing, comforting, approval, mirroring), while the suspiciousness motivated him to avoid or withdraw, behaviorally and emotionally. Therefore, he was highly conflicted about closeness, or even about establishing superficial relationships, unless approval and deep appreciation (and safety) could somehow be guaranteed.

Upon this defensive stratum rested another that addressed Marvin's painful self-concept directly, fueled in part by internalized family (of origin) expectations that he succeeds tremendously, attends the best schools and receive academic honors, become a CEO, and be the family's source of pride and healing; that is, he felt compelled to succeed to save the family from its shame or humiliation based on their immigration status (originally from Eastern Europe)—or else he risked drowning in his shame and humiliation (and theirs), as a disappointment and a failure. This painful internal terrain prompted him to adopt an idealized self-image as an elite super-achiever: An enterprising, enlightened, and inspired businessman who worked tirelessly, motivated colleagues and mentees, and accomplished what others could not. Other facets of this self-image were more compulsive; for instance, he worked to see himself—and be seen by others—as a serious-minded, disciplined, efficient, and industrious individual who was reliable and committed to work, productivity, and the bottom line. Accordingly, he was loath to appear frivolous or rash, terrified of making mistakes, or perceived as exercising

Telegram: @medical_k

www.konkur.in

poor judgment. Self-control was paramount; he presented as “buttoned up,” self-sufficient, and entirely in control of his needs, impulses, emotions, and behavior. Any acknowledgment or display of emotional pain or vulnerability would be too exposing, dangerous, shameful, and unbearable since, for him, it would be tantamount to broadcasting the inadequacy, weakness, and defectiveness he secretly felt but worked so intensely to escape or deny.

Given the stakes—instability of self-esteem/worth and the potential for excruciating exposure and shame—Marvin was compelled to extend his domain of control to include others. As suggested, this included managing his public and even private personas so that others only perceived what he wanted them to perceive (a superior, industrious, controlled super-achiever). In this way, he could have his greatness reflected, an unconscious psychological maneuver that effectively dispatched his most profound painful self-concept. Ideally, essential others (e.g., family members, mentees) would shine as well, as good reflections of him, but they were devalued or pushed away if they disappointed him or began to approach or eclipse his status. Marvin generally managed others by setting high expectations and being pushy and demanding. However, when his status or authority was challenged, control over others was somehow lost, or he felt disrespected, he was capable of direct or indirect retaliatory verbal aggression. These outbursts served to discharge his rage but also to push others back into line.

However, these measures intermittently failed during the “blue spells” or when stressors severely taxed Marvin’s limited coping resources. For example, when he had few mentees at work and felt less idealized. Alternatively, when a new junior manager publicly questioned his decisions, which challenged his sense of superiority and made him feel criticized, humiliated, and quietly furious. Similarly, when his adult children complained that he showed little interest in spending time with his grandchildren, he was left feeling criticized, ashamed, and resentful. These factors combined to motivate the “preretirement” to escape the painful work environment and have more opportunities to demonstrate that he was the “super grandpa” associated with his persona of exceptionality. However, he was unable to predict how the part-time consultant position would ultimately fail to “fill [his] sails,” provide worth and direction, neutralize his emptiness, and buttress his fragile sense of self (as inadequate, weak, defective, socially inept). He subsequently

Telegram: @medical_k

www.konkur.in

collapsed and was overrun by waves of regret and uncontrollable rumination about having made “the worst decision of my life!” Unfortunately, his defense of aloofness, superiority, self-sufficiency, and invulnerability made him a closed system, that is, he desperately longed for soothing, comfort, and relief from his pain within loving relationships wherein he is known but was unable to drop his armor. Ultimately, this has left him feeling dreadfully alone, misunderstood, resentful, and disillusioned with life, leading to his suicidal ideation and attempts.

Marvin’s assessment data and presenting symptomatology suggested the following diagnoses for consideration (from Diagnostic and Statistical Manual of Mental Disorders—5th Edition [DSM-5]): Major depressive disorder, recurrent; and other specified personality disorder with narcissistic and obsessive-compulsive personality traits.

Based on the assessment data, Marvin received treatment recommendations for short and long-term psychotherapy work. The team suggested that Marvin would benefit from time-limited cognitive-behavioral approaches (CBT) in the short term. These approaches could focus on modifying his painful intermediate and core beliefs (e.g., I am inadequate, weak, and defective; letting others see my vulnerabilities would be disastrous; anything less than being a super-achiever is an utter failure; I know best, so people should do things my way). These approaches could also help him retrain his attentional processes to register more accurate data that would allow him to develop reality-based, realistic, compassionate concepts of self and others.

In the longer-term psychotherapy work to initiate structural change (2 to 3× week psychodynamic psychotherapy), it was suggested that Marvin address his relationship templates and attachment style more immediately within the psychotherapy relationship itself—since they would inevitably surface there. After a basic alliance was established, the therapy focus could become more expressive, during which the therapist could explore Marvin’s feelings and relationship patterns more deeply. Given the nature of Marvin’s developmental arrest, it would be necessary for the therapist to communicate empathy about Marvin’s need for mirroring and to help him understand the links between (a) early deprivations, (b) his current hunger and emotional pain, and (c) the efforts to elicit signals from others that he is great, superior, admirable—including how he utilizes control to achieve this objective. It would also be imperative for the therapist to register and acknowledge their intermittent failures at providing this

Telegram: @medical_k

www.konkur.in

empathy. This cyclical therapy process—empathizing/mirroring, then recognizing and processing Marvin's painful feelings (e.g., grief, shame, humiliation, hopelessness, rage) when mirroring failures occur—would allow, over time, his current insecure sense of self to gain traction and resume its developmental trajectory.

PSYCHOTHERAPY. Marvin's individual psychotherapy consisted of a series of 15 sessions with a psychodynamic therapist, occurring three times per week throughout treatment. His original goals were to learn techniques to "manage the anxiety and depression and get back to have a contented life with my family"—a typical set of goals for the large subset of professional patients who present with a blend of compulsivity or perfectionism and narcissism. These individuals tend to fantasize that their struggles are mechanical problems that can be easily loaded into an algorithm that provides a quick solution. Not surprisingly, therefore, Marvin grumbled during the developmental history because he could not understand how his childhood experiences—including early, crucial attachment relationships—had any bearing on the current struggles. Similarly, he minimized the importance of addressing his recent suicidal ideation and suicide attempts because he no longer felt suicidal and was confident he would control any ideation and impulses that might occur again in the future. Consequently, he declined offers for a Collaborative Assessment and Management of Suicidality (CAMS) session.

He begrudgingly tolerated these deeper inquiries by the therapist but occasionally protested the lack of focus on immediate symptoms. A few times, he went so far as to suggest that the therapist was either incompetent or withholding effective (quick) treatments that were otherwise available. Here, Marvin responded moderately well to efforts by the therapist to highlight and challenge (a) his underlying fantasy that his mind is merely a contraption to be hacked and solved, and (b) his distorted perception that the therapist would be interested or motivated to withhold better treatments than were being provided. Marvin preferred to repeatedly describe his immediate psychiatric symptoms, such as anergia, anhedonia, low motivation, intermittent insomnia due to rumination, hopelessness, self-criticism, guilt, and regret, difficulty concentrating, and anxiety and tension secondary to catastrophic thinking. However, the most painful symptoms were the most difficult for him to describe and label. This process became a focus during the initial phase

Telegram: @medical_k

www.konkur.in

of psychotherapy. For example, he started making conceptual and emotional links between (a) the subjective emptiness, purposelessness, and worthlessness he felt overwhelmed by (and could now label) and (b) the decision to give up the CFO position that provided such buttressing and direction, but also opportunities to receive precious admiration and mirroring.

These insights paved the way for Marvin to begin noticing how robust was his use of control—to restrict his emotions, to ensure that others only ever perceived him as an astute leader, responsive mentor, and as an individual who was admirable, impressive, serious, disciplined, industrious, and entirely in control of himself. Marvin and the therapist explored how this defensive strategy manifested itself with family members, coworkers, in the milieu with fellow patients, and in the therapy relationship itself. For example, the therapist repeatedly pointed out when Marvin tried to impress her with tales about business adventures that indicated how accomplished, productive, and efficient he was; or when he tried to present himself as unusually informed about the epidemiology of specific mental disorders. Here, she made sure to interpret Marvin's tendency to present his super-persona as a desperate effort to flee direct contact with his deeper self-image as inadequate, weak, defective, and shameful. Around this time in the individual work, he received push-back from fellow patients about his aloofness, invulnerability, and efforts to impress. In concert, these external relational forces moved Marvin to begin softening his compulsive-narcissistic armor, which then paved the way for him to become a little more vulnerable, and therefore more willing to authentically express despair, regret, and sadness about having decided to preretire. Notably, only then did he become capable of making emotional links between the painful self-concept (defective, weak), his subjective experience of emptiness, and the pressure he felt to save the family (of origin) from their shame and humiliation about their immigration status by becoming a super-achiever.

These insights altered the trajectory of Marvin's healing journey. He eventually replaced his original psychotherapy goals ("manage anxiety and depression") with a set of more nuanced and sophisticated goals for the psychotherapy work while still on the professionals unit and going forward. These new goals focused on addressing his underlying sense of inadequacy, correcting his distorted perceptions of others, and reducing his reliance on compulsive-narcissistic armor. He also started to come to

terms with the fact that he lived most of his life feeling utterly responsible for saving the family system from shame and humiliation—and in the process, disowned or discarded parts of himself.

PSYCHOTHERAPY PROCESS GROUP. Throughout his treatment, Marvin attended a twice-weekly psychotherapy process group (80 minutes each session) based on a group-as-a-while interpretation model based broadly on the work of Wilfred Bion. In this adapted model, the group explores interpersonal communication, group dynamics, and group-as-a-whole processes, with particular attention to how the group manages anxiety about connecting in the here-and-now. Reliably, when group members feel safest, the group is most cohesive, so unconscious worries about the group's disintegration are in their lowest ebb—a condition that inclines group members to explore how they are relating to each other during the session. This level of connection requires the most significant vulnerability and is relatively rare because it involves exploring perceptions of each other and associated emotions in real time. This can include acknowledging and expressing caring and warmth, regret, sadness, hurt and anger, or envy. In this "safe" mode, group members are more inclined to share a great deal of detail about their internal struggles and the suffering that brought them to residential treatment.

In contrast, when group members feel less safe, the group is less cohesive, and unconscious worries about the disintegration of the group are ascendant—a mode that leaves members feeling insecure, too vulnerable to share details about their suffering, and more inclined to discuss superficial topics (e.g., the weather). Alternatively, they might unconsciously decide to complete the task of connecting in the here-and-now by forcing themselves into faux cohesion by finding a common enemy to rail against, for example, a political figure, a scapegoated staff member, the mental health system. Invariably, individual group members end up occupying roles (such as peacemaker, leader, outsider, helpless one) they adopted in their families of origin to reduce anxiety by nudging the process group toward cohesion or faux cohesion. In this model, the group "therapist" is not a facilitator, per se, but a consultant to working on the task. Consultations or interpretations are primarily directed toward the group-as-a-whole, for example, pointing out how the members have silently colluded to enlist one particular member to take up all the space with a monologue about his business history so that the group can avoid

Telegram: @medical_k

www.konkur.in

exploring and processing sadness they feel about the impending discharge of another beloved member. The ultimate goal of this approach is to help group members create the conditions for authentic connection and healing through emotional closeness and vulnerability. This goal is more likely to occur as group members learn more about how groups, in general, manage anxieties about working on a task and as each group member learns more about how they participate in these group-as-a-whole processes.

Given Marvin's defenses of aloofness, superiority, self-sufficiency, and invulnerability, he was slow to warm up to the psychotherapy process group experience. He declined initial offers by group members to share his reasons for coming to treatment. As they shared, he mainly remained quiet and disengaged, frequently looking out the large windows, lost in thought. After a few sessions, he began joining the group in some lighter conversations about experiences at work before treatment, though he limited his participation to noting some of his business accomplishments and describing how he has needed to "put some of my disrespectful underlings in their place." Members did not respond with open admiration, which frustrated him. Perhaps in response to this deprivation, he appeared to try moving into the role of wise elder by offering platitudes and problem-solving when members discussed their struggles. Some members were receptive and appreciative, while others saw through his defensive maneuvering and resented his superior stance, especially given that he had thus far avoided sharing anything deeply personal or painful. However, this resentment remained underground despite a few consultations about how the group seemed terrified of conflict and determined to ignore or deny palpable emotions in the room. Eventually, the dynamic shifted when the group added a new member (Libby) who was not particularly conflict-avoidant and was willing to articulate her frustration with Marvin about his persona of wisdom and invulnerability. In one group, she exclaimed: "You're like Gandalf or something, above it all…but I don't buy it. I think you're actually lonely. You'd have to be!" Her tone was both critical and caring. Marvin responded by referring to some of her recent dramatic behavior on the unit as "earth-mother histrionics." Other group members, emboldened by Libby's bravery, stepped into voice some of their pent-up frustrations about Marvin's superiority and inaccessibility, but also their desire to know him better, which he seemed to register. Notably, the discussion continued after the group ended and

Telegram: @medical_k

www.konkur.in

the consultant left the room. Three days later, much of the group tension was gone in the following group session, and Marvin began talking for the first time about the waves of regret and loss following his decision to preretire. His rumination and reassurance-seeking began to emerge, and members provided understanding and verbal support, which enabled him to become tearful during a later group session. In response to interventions in the group and milieu, he was becoming less of a closed system, for example, less aloof, more vulnerable, more able to allow himself to receive from others.

TERMINATION. After an 8-week stay, Marvin was asymptomatic. He left the hospital with an alternative plan of developing a part-time individual consulting practice and a self-help group therapy for higher managers going through burnout—it was an interesting outcome, a way of sharing his experience in the hospital with the less informed and perhaps less fortunate. On a personal level, Marvin continued his treatment with intensive psychodynamic work, group therapy, and medication management. Two years later, we had a call from him and learned that he was doing quite well.

Ethics and Forensic Psychiatry

58.1 Clinical-Legal Issues in Psychiatry

Clarence Watson, J.D., M.D., Spencer Eth, M.D., and Gregory B. Leong, M.D.

Among the medical specialties, psychiatry plays a particularly distinct role within the province of the law, given its potential application across a wide range of legal issues. Contained at the core of most legal principles is the general presumption that adults of sound mind possess the capacity to understand, appreciate, reason, and choose throughout a boundless range of life activities. When those mental capacities are called into question at the behest of a legal quandary, psychiatry may be summoned to assist with reaching an equitable resolution. The presence or absence of a mental health or cognitive disorder may significantly impact the manner that a legal issue, whether civil or criminal, is perceived and ultimately managed. For instance, the presence of major mood or psychotic symptoms may impact an individual's legal right to refuse a recommended surgical procedure. Similarly, the presence of significant psychiatric symptoms at the time of a criminal act may negate an individual's culpability for that offense. The enduring relationship between the law and psychiatry has evolved over the centuries as a necessary element of humankind's aspiration toward a just resolution of legal

Telegram: @medical_k

www.konkur.in

disputes. In no other place is this more evident than with the historical development of the legal concept of insanity in criminal law. Once reserved only for those individuals whose minds were equated with that of a wild beast, the legal concept of insanity has progressed to varied jurisdictional approaches in determining the degree of mental impairment necessary to absolve an individual of criminal responsibility. Equally as significant is the historical development of the doctor–patient relationship. Once considered a lopsided paternalistic arrangement, in which patients were expected to passively accept the medical care directed by their physicians, the doctor–patient relationship has matured into a dynamic interaction that centers on patients' autonomy, including a patient's right to refuse treatment.

From an eagle's eye view, the interplay between psychiatry and the law can be broadly divided into situations involving clinical treatment interactions and situations involving specific legal matters that require the input of psychiatrists to settle a contested legal issue. The complexities within this broad division cannot be overstated, and accordingly, the subspecialty of forensic psychiatry was, in essence, produced from necessity and the ever-developing legal landscape. Clinical-legal issues such as patient confidentiality, informed consent, the right to refuse treatment, and medical standards of care are ubiquitous in the psychiatrist–patient therapeutic relationship. Potential involvement by psychiatrists as experts in contested legal matters, such as criminal cases, personal injury lawsuits, employment-related claims, testamentary disputes, or child custody cases, requires familiarity with legal principles and jurisdictional laws and the ability to apply psychiatric knowledge to the relevant legal inquiry at hand.

Over the course of centuries, the unique pirouette shared between psychiatry and the law has at times lacked grace, but nonetheless, has steadily moved toward a more elegant cooperative existence. Often marked by tensions inherent in speaking different native tongues of the respective realms of medicine and law, the cooperative existence has benefited from both medical and legal literature aimed at bridging the gap. This chapter is meant to contribute to those literary efforts and offers common ground for the understanding of clinical-legal issues involving psychiatry.

THE DOCTOR–PATIENT RELATIONSHIP

Telegram: @medical_k

www.konkur.in

The concept of the doctor–patient relationship is naturally bound to the ancient roots of medicine itself. Evolving from a period when physicians were not distinguished from priests, magicians, or other ancient healers, the doctor–patient relationship initially resembled an archaic priest–supplicant relationship that hinged on a parental figure's power to manipulate nature on behalf of his ward. During the 4th century BC, the Hippocratic Oath set forth a code of ethics outlining principles that remain essential features of modern-day medical ethics, including patient confidentiality, abstaining from sexual contact with patients, and preventing harm to patients. The familiar dictum, *Primum non nocere* or first, do no harm, further distilled the fundamental ethical principle at the core of the doctor–patient relationship.

Clearly, at the heart of these traditional ethical doctrines, physicians are charged with acting only in the service of patients' medical benefit. The ethical principle of beneficence, where the ultimate medical benefit is paramount, was traditionally used to justify a paternalistic approach to medical care that was primarily physician-driven. However, during the late 19th and early 20th centuries, there was a growing sentiment that patients had the right to actively influence the course of their medical care. The concept of patient autonomy gradually gained ground and ultimately displaced the long-accepted institution of medical paternalism.

Patient autonomy was clearly endorsed in the 1914 case, Schloendorff v. Society of New York Hospital, which served as the figurative "canary in the coalmine" for medical paternalism in the dawn of an evolving informed consent doctrine. In that case, Justice Benjamin Cardozo ruled, "Every human being of adult years and sound mind has a right to determine what shall be done with his own body . . ." While not formally established in Schloendorff, the informed consent doctrine would become a more clearly defined legal requirement four decades later in the 1957 Salgo v. Leland Stanford Jr. University Board of Trustees case.

Certainly, at the inception of any doctor–patient relationship, there attaches a body of legal and ethical obligations owed by the physician to his patient. The shift away from medical paternalism toward the incorporation of patient autonomy permitted a more appropriate balance within the therapeutic relationship. Such a balance between a physician and his patient naturally facilitates a treatment partnership; however, there are clinical situations that call for prioritizing medical benefit over patient autonomy. Justice Cardozo's words in Schloendorff indicated his

Telegram: @medical_k

www.konkur.in

awareness of two important caveats regarding the “right to determine what shall be done” with one’s own body: adulthood and soundness of mind. It follows, of course, that the impact of existing psychiatric symptoms must be considered in the full clinical context when issues related to patient autonomy arise. Medical decision-making capacity, involuntary psychiatric treatment considerations, and patient confidentiality matters may all be influenced by the presence of significant psychiatric symptoms that temporarily deemphasize autonomy concerns.

MEDICAL DECISION-MAKING AND COMPETENCE

As initially framed in Salgo v. Leland Stanford Jr. University Board of Trustees, the law requires that physicians provide facts to their patients regarding treatment options that are “. . . necessary to form the basis of an intelligent consent.” Through this case law, the informed consent doctrine was established and formed a basis for physician liability when patient harm occurs in the setting of inadequate communication of the risks associated with treatment. In order to sufficiently obtain a patient’s informed consent, three elements must be present: the physician’s disclosure, the patient’s voluntariness, and the patient’s mental competence. Exceptions to the informed consent requirement include medical emergency, patient’s waiver of the physician’s disclosure requirement, and invocation of therapeutic privilege in situations where the disclosed information would be detrimental to the patient.

Generally, the informed consent disclosure requirement dictates that patients receive information regarding their diagnosis, the proposed treatment with the associated risks and benefits, treatment alternatives, and likely consequences of declining treatment. The 1972 case, Canterbury v. Spence, established that physician liability may be found if there is a causal connection between a physician’s failure to disclose and a patient’s injury, where the disclosure of the significant risks of treatment would have resulted in the patient’s refusal of that treatment. According to the court in Canterbury, that causal connection is based on “…what a prudent person in the patient’s position would have decided if suitably informed of all perils bearing significance.”

Depending on the state jurisdiction, the legal standard for an adequate disclosure may vary between a physician-based standard and a patient-based standard. In states that utilize a physician-based approach, doctors

Telegram: @medical_k

www.konkur.in

are required to provide information to patients that a reasonable physician in his specialty would disclose. States that utilize a patient-based approach may require an objective standard that considers the information that a reasonable patient similarly situated would want to know to reach a decision. Some states may require a subjective analysis of the patient-based standard that considers the information that the specific patient would want to know given their circumstances.

The voluntariness requirement directs that a patient be permitted to weigh the disclosed information and reach a decision unencumbered by coercion. Accordingly, threats, manipulation, or intentionally misleading information during a patient's decision-making efforts would nullify informed consent. A patient must be given the opportunity to freely consider the physician's disclosure and freely reach a medical decision.

The competency element requires that a patient possesses the mental capacity to understand, appreciate, and utilize disclosed information to reach a rational decision. Legally, all adults enjoy a presumption of competence in medical decision-making and other routine life activities until adjudicated otherwise. Traditionally, the term "competence" is a judicial determination regarding decision-making capability. Conversely, the term "capacity" refers to a clinical determination regarding a patient's decision-making abilities. Accordingly, the psychiatrist's role in competency evaluations is to determine an individual's mental capacity, which may later be formally adjudicated in a legal competency proceeding. In contested matters, courts have upheld the rights of a competent adult to refuse treatment. Courts may, however, adjudicate a person as incompetent if psychiatric symptoms or cognitive deficits impair an individual's mental capacity to communicate a choice, to demonstrate factual understanding and appreciation of his situation, or to rationally manipulate factual information related to his situation. In cases of adjudicated incompetence, treatment decisions generally shift from the patient into the hands of a substitute decision-maker or designated guardian.

Significant symptoms of mental illness or cognitive disorders are the typical culprits that undermine competence. However, the presence of those symptoms alone is not sufficient to establish a lack of mental capacity or to prove incompetence. In the 1973 case, In re Maida Yetter, a patient who was committed to a state psychiatric hospital refused treatment for possible breast cancer. Although delusional, the patient

Telegram: @medical_k

www.konkur.in

offered a rationale that justified her treatment refusal and allowed the court to determine that she was competent to make that decision independently and did not require a substitute decision-maker.

A controversial area related to medical decision-making capacity involves questions surrounding a terminally ill patient's right to die and physician-assisted death. Currently, ten states (Oregon, Washington, Vermont, California, Colorado, Hawaii, New Jersey, Maine, Montana, and New Mexico) and the District of Columbia legally permit physician-assisted death. In jurisdictions allowing terminally ill patients to choose physician-assisted life-ending measures, psychiatrists may be called upon to perform mental capacity assessments relating to those decisions.

INVOLUNTARY HOSPITALIZATION AND TREATMENT

Two traditional legal justifications, *parens patriae* and police power, provide state jurisdictions with the authority to involuntarily hospitalize or civilly commit mentally ill people for the purpose of treatment. *Parens patriae* refers to governmental power to care for individuals who are unable to care for themselves. The initial application of the parens patriae principle for the care of the mentally ill in the United States is found in the 1845 case, In re Oakes, which established the basis for courts to involuntarily hospitalize mentally ill persons for treatment and to prevent harm. The police power principle refers to the societal interest of permitting governmental authority to protect the general public from potential harm.

Jurisdictional statutes regarding involuntary psychiatric hospitalization vary from state to state but generally require the presence of a mental illness and a degree of risk of harm to the patient or to others due to the patient's symptoms of mental illness. Typically, the clinical determination for the necessity of civil commitment weighs a patient's current symptoms, relevant historical information, and collateral information sources (e.g., family members, friends, etc.) in the setting of a patient's inability or unwillingness to cooperate with the examination. During these assessments, the critical issue that must be addressed is whether patients' current psychiatric symptoms place them at risk of harming themselves or others. Additionally, some jurisdictions specifically require that involuntary treatment be implemented via the least restrictive alternatives available. Accordingly, clinical consideration must be given to

Telegram: @medical_k

www.konkur.in

alternatives to involuntary inpatient hospitalization, such as day treatment programs, group home placement, or other outpatient settings, depending on the circumstances.

Usually, these civil commitment assessments involve emergency situations in which family members, ambulance personnel, or police bring the patient to the emergency department because of concerns that the patient will imminently engage in suicidal, self-injurious, or violent behaviors. In addition, a voluntary patient might demand an immediate hospital discharge against medical advice and compel the psychiatrist to consider whether a civil commitment is necessary in lieu of discharge. Due to the urgency of these clinical situations, civil commitment laws permit clinicians to initiate involuntary emergency hospitalization without an initial court determination. This allows for immediate and necessary treatment interventions without the delay that awaiting a court hearing would cause. Following a statutorily determined period, a judicial review hearing is typically required to weigh the patient's need for continued involuntary hospitalization versus a patient's right to be discharged from inpatient treatment.

The legal standard of proof in civil commitment proceedings is "clear and convincing," which is less than the "beyond a reasonable doubt" standard in criminal trials. It is important to note that involuntary hospitalization does not per se permit medical treatment over patients' objections. Some jurisdictions require additional legal proceedings to permit the involuntary administration of medication over patients' objections. Following adequate treatment targeting the symptoms that necessitated the civil commitment, the patient may be discharged to the community to continue outpatient treatment. In some states, patients with extensive histories of treatment nonadherence and frequent hospitalizations may be evaluated prior to discharge for the appropriateness of outpatient civil commitment in order to improve community functioning.

In addition to standard civil commitment laws for psychiatric treatment, some states have enacted specialized civil commitment laws for the involuntary treatment of violent sex offenders who continue to pose a risk of danger following incarceration. In 1997, the U.S. Supreme Court upheld the constitutionality of sex offender civil commitment laws. Under these specialized provisions, these convicted and incarcerated sex offenders are evaluated prior to their prison release to determine if commitment

Telegram: @medical_k

www.konkur.in

criteria are present, including the existence of a congenital or acquired mental abnormality, the number and severity of previous sexual offenses, and dangerousness.

Psychiatrists cannot lose sight of the inherently intrusive nature of involuntary treatment. Accordingly, clinicians are ethically obligated to exercise due diligence in obtaining all relevant clinical data prior to determining the need for civil commitment. The psychiatrist continues to bear the ethical obligation of avoiding unnecessary breaches of patient confidentiality. However, testimony and communications to mental health courts required by law for the purpose of civil commitment are permitted without patient consent. Nonetheless, clinical efforts to preserve patient dignity and foster a therapeutic alliance with the patient remain paramount.

CONFIDENTIALITY AND PRIVILEGE

Confidentiality and privilege are related concepts that center on privacy rights belonging to patients regarding information shared with their physicians during the course of therapeutic relationships. Confidentiality represents physicians' obligation to their patients to not disclose information to third parties without a patient's consent. Privilege also deals with the protection of patient information; however, it refers to the more specific protection against physicians being compelled to provide protected patient information during court proceedings. Privilege is a right that specifically belongs to the patient, in that a physician cannot claim the privilege and refuse to disclose patient information once a patient has waived the privilege.

The doctrine of patient confidentiality is an ethical and legal duty that has been long recognized throughout the tradition of medicine, as evidenced by the Hippocratic Oath's charge to preserve patient privacy. Certainly, it is not difficult to understand the basis for this duty. The very nature of the doctor–patient relationship prompts patients to trust physicians with intimate details of their lives, relationships, and bodies for the purpose of medical treatment. Patients' candid communication of these details facilitates effective medical treatment and would likely be discouraged if physicians were free to reveal those details publicly.

Physicians may be held liable for breaches of patient confidentiality through legal theories of medical malpractice, invasion of privacy, and

Telegram: @medical_k

www.konkur.in

breach of contract for implied warranty of confidentiality. State legislatures have also enacted statutes that prohibit the unauthorized release of patient information. Accordingly, physicians may also be held liable for the breach of statutory duty of confidentiality. In addition, the U.S. Congress enacted the Health Insurance Portability and Accountability Act of 1996 (HIPAA), which provides a set of privacy regulations that govern the electronic transmission of health information for insurance eligibility and billing purposes. Psychiatrists should note that the practice of telepsychiatry also falls under HIPAA regulations. Accordingly, psychiatrists must ensure that their videoconferencing systems are compliant with HIPAA and state privacy requirements. Violations of HIPAA privacy regulations call for the imposition of fines. However, these regulations do not provide compensation to patients impacted by confidentiality breaches.

There are several exceptions to the confidentiality duty owed to patients by their psychiatrists. First, disclosures by psychiatrists without patient consent may be permitted in emergency situations in order to prevent imminent harm. Second, psychiatrists may breach confidentiality when acting to protect third parties from a potentially dangerous patient. In 1976, the California Supreme Court decided Tarasoff v. Regents of the University of California, which set into motion a nationwide trend establishing the duty of mental health professionals to protect or warn their patients' potential victims or to notify police of a risk of danger posed by a patient. Laws regarding the duty to warn or protect third parties vary by state jurisdiction and are defined by state statutory and case law. These laws provide an avenue for clinician liability if harm befalls a third party as a result of a mental health professional's failure to disclose the danger posed by their patient. Generally, disclosures made in good faith for the purpose of protecting the third party will not result in liability for breach of confidentiality. Third, psychiatrists may disclose patient information when adhering to state reporting requirements involving concerns such as child or elder abuse, unsafe drivers, or impaired health care professionals.

The physician–patient and psychotherapist–patient privilege doctrines evolved from the historical legal prohibition of compelled testimony from attorneys against their clients. The basis of that legal tradition was to protect the sanctity of the attorney–client relationship, which would be effectively eviscerated if lawyers could be forced to testify against the very

Telegram: @medical_k

www.konkur.in

clients that they represented. Much like the justification for requiring patient confidentiality, the physician–patient, and psychotherapist–patient privilege facilitate a more open and effective therapeutic alliance. In all state jurisdictions, patients possess the legal privilege to prevent their psychiatrists and psychotherapists from testifying about them. Federal courts also recognized patients' privilege following the U.S. Supreme Court's 1996 ruling in Jaffee v. Redmond. As the privilege belongs solely to the patient, psychiatrists have no basis for refusing to testify if their patients choose to waive that privilege.

However, the privilege is not absolute and may be pierced under a number of circumstances, thereby paving the road to compelled testimony by treating psychiatrists. Patients may lose the privilege in cases where they raise their mental status as an issue in a civil or criminal matter. Medical malpractice claims initiated by patients against their psychiatrists or therapists would also remove the privilege. The privilege does not apply in civil commitment proceedings. In child custody cases, the privilege may be set aside if the best interests of the child outweigh the negative impact of the psychiatrist's testimony. Finally, the privilege could be potentially nullified if the patient shared the information in question with their physician in the presence of a third party who is not involved in the patient's care.

PSYCHIATRIC MALPRACTICE

Psychiatrists tend to dread malpractice lawsuits in excess of the statistical likelihood of being sued and having a judgment entered against them. Across all medical specialties, there has been a major reduction in the rate of paid malpractice liability claims during the last decade, which, unfortunately, has not been accompanied by commensurate decreases in the cost of malpractice insurance policies. There are approximately ten paid claims for every 1,000 American allopathic physicians each year. By contrast, however, the Institute of Medicine estimates that more than 100,000 Americans die annually from medical mistakes, and about 6% of patients are injured by medical mismanagement. Recent data reveal that among an extremely large sample of physicians, malpractice actions cluster in a relatively small percentage: 89% of physicians had no malpractice claims, about 9% had only one claim, while the remaining 2% or so had two or more claims that amounted to nearly 40% of the total

Telegram: @medical_k

www.konkur.in

claims. Psychiatrists experienced about 4% of all claims, commensurate with their representation of 3.6% of the total sample of physicians.

About half of malpractice claims filed are litigated. Of these claims, courts dismiss more than half, and another 40% are resolved before a trial verdict. The remaining small minority of cases become jury trials, of which 80% result in a defense verdict favoring the physician. Nationally, the mean time for resolution of a litigated malpractice claim is 2 years, which has grown considerably because of the backlog of cases associated with COVID restrictions affecting many aspects of the legal process, particularly jury trials. In one large state, about 2% of all malpractice settlement reports were for psychiatrists, compared with 9% for internists and 10% for general surgeons. The majority of malpractice actions filed against psychiatrists derive from accusations of negligent treatment, adverse effects of prescribed medications, and suicidal and assaultive behavior of patients. The remainder mostly concerns alleged mistakes in diagnosis, breaches of confidentiality, and boundary violations. A psychiatrist's participation in a malpractice settlement exceeding a threshold amount will result in a mandatory report to the federal National Practitioner Data Bank (NPDB), an entity that was first authorized in 1986 as a repository for information such as adverse licensure and hospital actions, and health care providers' malpractice payments. NPDB entries are routinely accessed by hospitals and licensing boards and may trigger inquiries that cause discomfort for physicians who may have felt unfairly coerced to agree to a settlement.

The theory of medical malpractice refers to professional negligence that falls within the civil law domain, as defined by state statutes and case law. For example, in Florida, patients or their representatives may file lawsuits for personal injury or wrongful death against health care providers. In those malpractice actions, plaintiffs must prove by a preponderance of the evidence that the actions of the provider represented a breach of the prevailing professional standard of care. The standard of care in this context is a legal term that refers to skillful treatment, which in light of all relevant circumstances, is recognized as acceptable and appropriate by reasonably prudent providers in the same specialty, such as practicing psychiatrists.

The law recognizes that the mere existence of an injury does not automatically imply that provider negligence occurred without proof that the provider did, in fact, breach the standard of care. A bad outcome does

Telegram: @medical_k

www.konkur.in

not per se equate to bad care. An exception to this rule is the legal concept, *res ipso locquitor* or the thing speaks for itself, where the commission of an egregious error, such as failing to remove an abdominal clamp during surgery, shifts the burden of proof from the plaintiff to the defendant physician to show that negligence did not occur. For psychiatrists, such an egregious error would certainly include sexual misconduct during a therapy session under the guise of treatment.

The necessary elements for patients to successfully establish malpractice claims have been neatly summarized as encompassing four D's: duty, dereliction, direct causation, and damages. The duty element requires that a doctor–patient relationship had been established, thereby creating a duty of care. Although seemingly straightforward for most treatment situations, there are some instances in which the nature of the professional relationship can be vague. Does a duty begin with the first contact between a potential patient and psychiatrist setting an appointment over the phone or only after the initial in-person or telehealth virtual platform meeting? When does the duty terminate? Does a covering physician assume responsibility for a patient if the patient calls for a medication refill or is seen briefly on rounds over the weekend?

The element of dereliction refers to a breach of the duty to provide reasonable and appropriate care. Psychiatrists are not legally expected to offer perfect, state of the art, or even excellent diagnostic and treatment services. All that is required is for the psychiatrist to perform as would other psychiatrists facing the same patient. Being board certified in psychiatry is neither necessary nor sufficient to establish that no deviation from the standard of care has occurred. It may be useful to demonstrate compliance with authoritative treatises, such as the Comprehensive Textbook of Psychiatry, recent peer-reviewed publications, or professional association treatment guidelines. However, it is an accepted principle that every person is unique and, consequently, patient-centered care may call for modifications in the usual therapeutic approach. Prescription medications are dispensed with package inserts containing information drug companies have submitted to the Food and Drug Administration (FDA). However, physicians are under no legal requirement to adhere to what is in the package insert and have substantial deference in prescribing "off label" as called in their clinical practices. Indeed, perhaps half of patients prescribed the common psychotropic medications are receiving them for off-label indications. Accordingly, a clinical judgment

Telegram: @medical_k

www.konkur.in

that adequately accounts for a patient's full clinical context, despite an eventual bad outcome, would likely assist in buffering against a claim of dereliction. When proposing an unusual treatment plan that may be later questioned, the psychiatrist would ordinarily be expected to obtain informed consent from the patient. The details of the consent discussion should be carefully inscribed in the medical record, and it may be helpful for patients to sign a note documenting their understanding and agreement.

The direct causation element requires a direct causal connection between a breach of the standard of care and a subsequent patient injury. The term "causation" is one that may have conceptually different meanings in medicine and law. For scientific-minded physicians, a cause–effect relationship identifies that a particular prior event is the physical cause if it results in the later effect. The law takes a very different approach. The salient issue is the proximate cause, by which the focus of the legal inquiry is whether the act in question was necessary to produce the injury. A common test for direct causation is whether the harm would not have occurred "but for" the prior action.

Legal commentators have argued that direct causation is that necessary element of a set of conditions that are jointly sufficient for the result. For example, a psychiatrist's older adult patient endorsed symptoms of depression, weakness, postural instability, and osteoporosis. The patient fell to the floor while rising from the office couch at the end of a session and immediately complained of severe pain. The patient was taken to a local hospital emergency room and diagnosed with a hip fracture. Surgery was performed, but the patient developed a postoperative infection that ultimately proved fatal. This tragic chain of events undoubtedly had multiple underlying medical causes. However, from a legal perspective, the psychiatrist could be found to be negligent and the proximate cause for all of the patient's subsequent injuries and death. Depending on the facts, the crux of the matter may be that, but for the mishap while rising from the psychiatrist's couch, the patient would not have had a broken hip, surgery, an infection, and death. In this regard, the patient was surely an "eggshell" whose fall was the "straw that broke the camel's back." As lawyers are fond of saying, one takes plaintiffs just as you find them.

The damages element refers to the plaintiff's alleged injuries that resulted from the physician's dereliction of duty. Civil law recognizes

Telegram: @medical_k

www.konkur.in

several categories of damages that may accrue to victims of malpractice, all of which are exclusively financial. Monetary awards to successful plaintiffs are intended to compensate the plaintiff for the harm suffered. Compensatory damages address what the patient has suffered as a direct consequence of the substandard care and include present and future medical costs, lost income, physical and mental impairment, pain and suffering, and decreased life expectancy. Punitive damages, also known as exemplary damages, may be awarded in addition to compensatory damages when a defendant's behavior was found to be particularly egregious or malicious. Punitive damages are not meant to compensate a plaintiff's loss; instead, they are meant to punish the defendant and to serve as a deterrent to the defendant and others regarding similarly wanton behavior. Punitive damages, which are not covered by insurance, rarely arise in malpractice actions against physicians.

The specter of serial medical malpractice claims, analogous to mass tort litigation, became a grim reality in the aftermath of the conviction of a Michigan State University (MSU) sports physician for sexually abusing multiple young women under the guise of treatment. MSU agreed to pay $500 million to 332 alleged victims, thereby settling their lawsuits without a trial. The University of Southern California (USC) was faced with at least 1,700 claims of sexual misconduct during gynecologic examinations by a physician practicing for many years in the campus student health clinic. The two negotiated and court-approved settlements for the USC student plaintiffs totaled $1.1 billion. These universities had employed the physicians and were thus ultimately responsible for the damages inflicted under the legal theory of *respondeat superior* that holds an employer liable for employees' wrongful or negligent acts. The "deep pocket" universities were the target of civil legal action, while the physicians were pursued separately and aggressively by the criminal justice system.

Certain aspects of psychiatric practice involve a greater risk of liability. Electroconvulsive therapy (ECT) is a procedure that usually calls for additional training and special precautions and may be associated with a greater likelihood of adverse events than conducting a psychotherapy session. Consequently, psychiatrists who wish to perform ECT may need to purchase insurance policies that specifically cover this procedure. Prescribing certain psychiatric medications also warrants a cautious approach. Conventional antipsychotic medications place patients at risk of developing tardive dyskinesia, which, when severe, can be disfiguring and

Telegram: @medical_k

www.konkur.in

disabling. Successful malpractice cases have been filed when psychiatrists failed to alert patients of this side effect risk and neglected to perform and document routine examinations for its detection. Similarly, the use of atypical antipsychotic medications may call for routine assessments for weight gain and abnormalities of blood lipid and glucose metabolism in addition to patient discussions regarding these associated treatment risks. Increasingly, psychiatrists use formal education materials to supplement informed consent discussions when prescribing common psychotropic medications, such as benzodiazepines, stimulants, and lithium.

The specter of patient suicide affects all practicing psychiatrists; indeed, it is a truism in the field that there are two kinds of psychiatrists—those who have already had a patient commit suicide and those who will. Rather than encouraging fatalism, the ever-present danger of suicide for certain groups of patients should motivate psychiatrists to remain cognizant of the basic suicide-reducing strategies. Knowledge of the evolving epidemiology of suicidal behavior is fundamental in assessing static and dynamic risk factors for each patient. There is no question that asking patients about the presence and severity of depressive symptoms and suicidal thoughts is essential for proper care. Such direct inquires do not suggest to or predispose a patient to become actively suicidal. The Joint Commission has suggested the implementation of standardized suicide risk assessment instruments, such as the Columbia-Suicide Severity Rating Scale (C-SSRS), that can be embedded as mandatory fields in electronic note templates so that clinicians must explicitly address the issue of suicidal ideation in settings such as the emergency room. Psychiatrists must respond to the escalating risk of suicidality with very careful monitoring and appropriate modifications in the treatment plan.

No discussion of psychiatric malpractice is complete without consideration of boundaries. Much has been written about the conscious and unconscious forces that are in play in both patient and psychiatrist during a session, especially in the context of psychotherapy. Maintaining the integrity of the therapeutic frame, however challenging, is the linchpin of treatment. Of particular concern are boundary violations that constitute frank lapses in care, such as psychiatrists becoming romantically involved with a current or former patient. This boundary violation is usually characterized by a progression from a seemingly innocent conversation, to more frequent social contacts, to physical affection, to sexual activity. In

Telegram: @medical_k

www.konkur.in

these cases, psychiatrists can exhibit remarkable denial regarding the serious consequences of their own behavior. Not infrequently, a transgressing psychiatrist, such as one who may be lonely, depressed, and substance-abusing, begins a destructive relationship with a vulnerable patient, whose judgment may be impaired by an idealizing transference and self-defeating tendencies. Such unethical behavior may result in malpractice and licensing board actions that jeopardize a professional career.

THE PSYCHIATRIST AS AN EXPERT

Expert Witness Testimony

Psychiatrists may be asked to participate in civil and criminal court matters by providing professional opinions based on their psychiatric knowledge and experience as applied to a particular legal question. Typically, the opinions are provided to a requesting party, generally the court or an attorney, either as a written or oral report. In some instances, the opining psychiatrist is required to testify in court, with a jury or judge considering such testimony along with other evidence in order to reach a verdict. Psychiatric expert testimony takes place in the public purview and is often viewed by the public as a “battle of the experts” or, more pejoratively, battle of “hired guns.”

In some cases, expert witness testimony is legally required, such as in cases involving allegations of medical malpractice. For example, in order to support a medical malpractice claim that a defendant psychiatrist’s treatment led to a patient’s suicide, the plaintiff must present expert testimony to show what a psychiatrist of ordinary skill, care, and diligence would have done differently under similar circumstances. Of course, should this malpractice case go to trial, there may also be psychiatric expert witnesses testifying on behalf of the defendant psychiatrist. Two court cases have governed the admissibility of scientific expert testimony in the United States, Frye v. United States and Daubert v. Merrell Dow Pharmaceuticals, Inc. As both cases indicate, it is ultimately the judge’s decision as to the admissibility of the expert witness testimony.

Role Conflict as a Psychiatric Expert Witness

Telegram: @medical_k

www.konkur.in

The fundamental professional role of psychiatrists involves a clinical or therapeutic perspective. In the clinical or therapeutic setting, the treating psychiatrist deals with the patient's narrative truth and makes no further attempts at confirming a patient's statements. In contrast, when a psychiatrist works outside of the health care setting in the legal arena, the clinical or therapeutic perspective loses its primacy, and an individual's self-report should be viewed with objectivity and hence skepticism. Assuming both the therapeutic and expert witness roles for the same individual invite erosion of the psychiatrist–patient relationship, whether it involves completing a disability evaluation in which the treating psychiatrist does not find support for the requested disability, or especially in the case of testifying in court as a psychiatric expert witness.

Separating the therapeutic and forensic roles is the best solution, though, at times, the dual role cannot be avoided, as in the case of involuntary civil commitment or involuntary medication hearings in which the treating psychiatrist is usually the only professional to testify. There are times in which a treating psychiatrist could be called to testify as a fact witness regarding a patient, but this would entail testifying about symptoms, diagnosis, prognosis, and similar clinical matters versus providing the ultimate psychiatric-legal opinion such as those involving capacity or causation.

Testamentary Capacity

With the growth of the older adult population, psychiatrists are being confronted with an increasing incidence of its emblematic mental condition, dementia, and the related clinical-legal issues of capacity and competence. Although adults are assumed to have capacity for the various activities of daily living and life tasks, that presumption is rebuttable, especially in the presence of neurocognitive impairment. Each specific deliberative legal act, such as testifying in court as a witness, executing a financial transaction, and even getting married, has its own criteria for mental capacity that must be satisfied in order for that action to be valid. Among the older adults, the process of writing a last will and testament is a common and highly valued event that has important implications that will arise after the death of the testator.

Legislatures and courts recognize that making a will is frequently in the province of persons whose mental acuity is significantly less than young individuals engaged in other tasks. Consequently, the cognitive standard

Telegram: @medical_k

www.konkur.in

for testamentary capacity is generally set particularly low. In most jurisdictions, the necessary elements are that persons understand: (1) the fact that they are actually making a will, (2) the nature and extent of their property, (3) the disposition of that property, and (4) who are their natural heirs. From a mental status perspective, this domain of knowledge does not require that the person making the will is fully oriented and, indeed, having the diagnosis of Alzheimer disease per se would not disqualify a person from having sufficient cognitive ability to make or change a will if the criteria for testamentary capacity could be established.

Although simple to state, the prerequisite criteria for testamentary capacity may be, in practice, quite difficult to ascertain after a person's death when the will is finally read. For instance, a person could have been suffering from severe dementia at the time of death. However, the document was actually prepared years earlier, and it is the state of mind at the time when the will was written that is dispositive if the document is later contested. A retrospective assessment conducted after death is challenging when there is inadequate evidence of the individual's prior knowledge and abilities. Medical records, deposition testimony from relatives and acquaintances, and information about activities of daily living can contribute to a determination of capacity.

Since wills may be the product of debilitated older adult persons who depend on the physical and medical care of others, there is another requirement that must be satisfied before the terms of the will are honored. Testamentary capacity demands that the testator not be subject to the undue influence of another person. For example, the philanthropist Brooke Astor died at the age of 105 in 2007. Her older adult son was convicted in criminal court of preying upon his mother's diminished mental state by defrauding her in life and coercing her to change her will in his favor rather than directing her assets to her favorite art institutions. An adult child who spends considerable time with a vulnerable parent may be expressing love and devotion. Alternatively, that situation may be exploited to benefit the child at the parent's expense.

Psychiatrists may be asked to opine whether a litigant heir exerted control over the person making a will. Certainly, whether there existed a confidential relationship and whether the will was rewritten to inappropriately benefit that person are critical factors. In this setting, a "confidential relationship" between two individuals occurs when one of the parties has an obligation to act in good faith for the benefit of the other

Telegram: @medical_k

www.konkur.in

party. The psychiatrist's expertise will be most relevant to the question of the extent to which the testator was vulnerable to being influenced due to medical or psychiatric illness and the power of the asymmetric relationship.

Criminal Competencies

The presence of competent decision-making is necessary for a criminal defendant navigating the criminal justice process, starting from the initial arrest to the implementation of the death penalty. While competence is presumed for adults, the presence of a mental disorder may negate competence. The criminal competencies include: competency to waive Miranda rights, competency to confess, competency to stand trial, and competency to be executed.

The U.S. Constitution and its Amendments, along with subsequent federal and state case law and statutes, delineate the legal safeguards for individuals accused of committing crimes. At the entry point into the criminal justice system, law enforcement officials must inform a criminal suspect of their Miranda rights, such as the right to remain silent and the right to counsel. The presence of an active mental disorder or intellectual disability can negate an individual's capacity to voluntarily, knowingly, and intelligently waive their Miranda rights. Though very few adults lack the capacity to waive their Miranda rights, the majority of incompetence to waive Miranda rights involves juveniles where factors such as immaturity and emotional vulnerability are more likely to adversely impact voluntariness, knowledge, and/or intelligence. The competency to confess might be considered under the broader competence to waive Miranda rights. In 1986, the U.S. Supreme Court in Connelly v. Colorado ruled that absent physical coercion by police, an actively psychotic individual, who approached a police officer to confess about committing a homicide as a result of command auditory hallucinations to confess, had provided a valid confession.

The most common forensic psychiatric evaluation in the criminal justice system is that of competence to stand trial. The criteria for competence to stand trial is guided by several U.S. Supreme Court decisions, with two having the most significance, Dusky v. U.S. (1960) and Godinez v. Moran (1993). The Dusky case established that competency to stand trial is composed of two prongs: (1) understanding of the criminal proceedings; and (2) reasonable ability to consult with defense counsel. In the Godinez

Telegram: @medical_k

www.konkur.in

case, the court ruled that if criminal defendants are competent to stand trial, they are also competent for other activities in criminal proceedings, such as the competence to waive counsel, competence to enter a plea (waive trial), and competence to be sentenced.

For jurisdictions that permit capital punishment, the U.S. Supreme Court has mandated certain exclusions to the imposition of the death penalty, including mental retardation (now referred to as Intellectual Disability in the DSM-5-TR) in Atkins v. Virginia in 2002 and for those under age 18 at the time of committing the capital offense in Roper v. Simmons in 2005. The U.S. Supreme Court in Ford v. Wainwright in 1986 and Panetti v. Quarterman in 2007 prohibited the execution of condemned inmates who are incompetent to be executed. Incompetence to be executed involves a condemned inmates' inability due to a mental disorder to understand the death penalty and the reason it is being imposed on them. Although cases of competence to be executed are quite rare, it has raised several ethical issues for society and the medical profession.

Criminal Responsibility and Psychiatric Illness

The determination of culpability and subsequent societal sanctions for those committing a criminal act finds its origins at least as far back as the dawn of recorded human history, along with considerations given to those with abnormal mental conditions. The evolution of English law in the area of criminal responsibility of the mentally disordered over the past millennium has exerted great influence on how criminal responsibility has been determined in the United States. Although the number of psychiatric evaluations for defendants claiming that a mental condition negated their criminal responsibility for an offense accounts for a small proportion of evaluations performed for the criminal justice system, the issue of criminal responsibility of those with mental disorders is arguably the most visible to the general public due to extensive media coverage, both fictional and nonfictional.

To be proven guilty of committing a crime, the prosecution must prove beyond a reasonable doubt that the accused person not only committed a prohibited act (*actus reus*) but also had the requisite mental state or "guilty mind" (*mens rea*) for the forbidden act.

The insanity defense is used to prove that an individual did not possess the necessary mental state for criminal responsibility due to mental illness at the time of the act. From the preceding millennium, the concepts of the

Telegram: @medical_k

www.konkur.in

"wild beast test" and the ability to distinguish between good and evil (right and wrong) represented society's efforts to legally define "insanity." These efforts evolved and culminated in the formulation of the M'Naghten insanity standard in 1843 by the English House of Lords following an insanity acquittal in the English trial of Daniel M'Naghten. The M'Naghten insanity test required the defendant to prove that they were "laboring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing; or, if he did know it, that he did not know he was doing what was wrong." The M'Naghten standard was quickly adopted for use by the U.S. judicial system. The federal government, the District of Columbia, and 46 states permit some form of the insanity defense. Among the 46 states that permit the insanity defense, approximately half use a M'Naghten type of insanity test. Four states (Montana, Idaho, Utah, and Kansas) disallow the insanity defense. In 2020, the U.S. Supreme Court affirmed that states are not required to provide an insanity defense (Kahler v. Kansas).

While the majority of state jurisdictions use the M'Naghten insanity standard, some states use other insanity tests. Currently, the most common other type of insanity test is that of the American Law Institute (ALI). To qualify for insanity under the ALI insanity test, a criminal defendant must demonstrate that as a result of a mental disorder, they lack "substantial capacity to either appreciate the criminality of his conduct or to conform his conduct to the requirements of the law" (Model Penal Code §4.01, 1962). When comparing the two current major insanity tests used in the United States, the M'Naghten test has two "cognitive" prongs (knowledge of the "nature and quality" and "wrongfulness") versus ALI's one "cognitive" prong ("appreciate the criminality") and one "volitional" prong ("conform conduct"). Interestingly, some states that use an ALI-type of insanity test do not use the "volitional prong," thereby functionally making the insanity standard more like the M'Naghten test. Wording differences between the M'Naghten and ALI insanity tests would suggest that an insanity defense would be more likely successful in jurisdictions using the ALI insanity test.

In actuality, the overall use of the insanity defense is infrequent. The defense is raised in approximately 1% of felony cases with an estimated 25% success rate. The vast majority of insanity acquittals involve prosecutorial concurrence prior to trial. It is estimated that juries reject the insanity defense in 93% of cases going to trial. It has been argued that the

Telegram: @medical_k

www.konkur.in

legal system's requirement to not inform juries of the potential legal consequence of an insanity acquittal, that is, that a defendant acquitted by insanity would not be automatically released into the community, but would be subject to commitment in a state mental health facility, adversely impacts jurors' willingness to accept insanity defenses.

CHILDREN AND THE LAW

Children and adolescents can become enmeshed in the U.S. legal system in a multitude of ways, some of which are comparable to adults, and some are fundamentally different. In fact, the number of youth involved in court actions has increased dramatically, driven by criminal activity in gangs and on their own, by the escalating rates of foster care, divorce, and custody disputes, and by the proliferation of child abuse neglect, and victimization. Further, there continues a veritable parade of personal injury lawsuits filed on behalf of child victims that alleged harm from sexual misconduct by generations of clergy, teachers, and others. Psychiatrists would benefit from a familiarity of the basic concepts of children and the law, if for no other reason than to better understand their adult patients whose early histories may be replete with such encounters and whose younger family members may become entangled in some aspect of the law.

Children, Juvenile Justice, and Violence

Juveniles can be both perpetrators and victims of crimes. The indisputable developmental differences between prepubertal children and adolescents, and especially adults, have legal implications insofar as cognitive phase-specific limitations of youth accused of criminal behavior would seem to necessitate special measures if not an entirely different method of adjudication. Indeed, states created parallel juvenile justice systems for youthful offenders that, in many ways, were responsive to the developmental immaturity that characterizes children and younger adolescents. In 1899, Illinois established the first juvenile court separating the adjudication and confinement of youth as delinquents from the conviction and imprisonment of adults as criminals. The scope of juvenile courts expanded to encompass both criminal acts and behaviors that would not be considered illegal for adults, such as curfew violations, drinking alcohol, and truancy, which have been called status (as a minor) offenses. The rationale for juvenile courts' broad jurisdiction is the

Telegram: @medical_k

www.konkur.in

promotion of social warfare by prioritizing education and rehabilitation rather than punishment.

Every state proceeded to adopt a system of juvenile courts, whose procedures were then significantly modified by the Supreme Court's landmark cases under Chief Justice Earl Warren. In 1967, the U.S. Supreme Court held that, although it was permissible to treat juveniles and adults differently in court, youthful offenders facing possible incarceration are entitled to the same constitutional rights of notice of charges, counsel, protection from self-incrimination, and the opportunity to confront and cross-examine witnesses, as afforded to adults. Three years later, the Supreme Court also ruled that the "beyond a reasonable doubt" standard of proof also applied in juvenile court. Extending constitutionally based procedural rights to juveniles did not imply that juveniles could escape conviction and punishment, especially if they committed serious crimes. Prosecutors have the discretion to file for a judicial waiver that moves the youth from juvenile court to adult court in order to deny the protections that juvenile jurisdictions provide, including the preclusion of long prison sentences.

Most states exclude first-degree murder charges from the juvenile system, which for many years effectively allowed a convicted juvenile murderer to be sentenced to execution. The eligibility of a person who committed their crime as an adolescent for capital punishment proved to be controversial even among death penalty advocates. The Supreme Court reviewed the question of juvenile capital punishment and decided in Roper v. Simmons (2005) that defendants were not eligible for execution if their crimes were committed under the age of 18 years. The court's opinion in this decision drew heavily on scientific data concerning neuropsychological development that contrasted adolescents with adults, which were presented in amicus briefs submitted by psychiatric and psychological professional organizations. Five years later, the Court, in Graham v. Florida (2010), held that the U.S. Constitution prohibits sentences of life without parole for juvenile offenders who did not commit homicide. In those cases, a juvenile offender is not guaranteed eventual release, but if a life sentence is imposed, the juvenile must be afforded a realistic opportunity to obtain release before the end of that sentence. In Miller v. Alabama (2012), the U.S. Supreme Court extended its reasoning to preclude as unconstitutional a mandatory sentence of life without the possibility of parole for juveniles convicted of homicide offenses.

Telegram: @medical_k

www.konkur.in

The Columbine High School tragedy in 1999 engendered an awareness of a looming threat of mass killings occurring in a school, possibly perpetrated by an adolescent or young adult. Despite heightened vigilance of the danger of a lethal attack on campus, a mentally ill college student at Virginia Tech University in 2007 murdered 33 persons, and in 2012 a mentally ill adolescent opened fire on and mortally wounded 20 children at the Sandy Hook Elementary School in Connecticut. More recently, in February 2018, a 19-year-old former student expelled from Marjory Stoneman Douglas High School in Parkland, Florida, killed 17 people in that school. There have been strident demands to develop strategies to profile potentially deadly students who may be targeting schools for deadly violence. Youths with the risk factors of a history of psychiatric illness, aggression, suicidal behavior, and/or family strife and who have access to weapons may indeed be at a higher likelihood for violence. However, less than 5% of crimes overall can be attributed to mental illness. Identifying those individuals at risk with any degree of certainty must overcome the daunting challenge of the high false-positive rate associated with predicting a rare event.

Most experts are skeptical of the wisdom of deploying armed security in elementary and high school buildings. Further, implementing zero-tolerance policies for aggressive behavior may disproportionally impact minority, disadvantaged, and special needs students who generally benefit the least from suspensions or expulsions. Alternatively, school-based interventions designed to decrease bullying and stigma, provide enhanced access to students for counseling and mental health care, expand communication among students, faculty, and parents, and eliminate or at least safeguard guns in the home all hold the promise of more effectively addressing the threat of interpersonal and self-inflicted violence.

Child Custody

Each year in the United States, there are about half the number of divorces as there are marriages. Divorce proceedings sever the marriage contract between spouses, and although children may be a focus of the case, they are not considered formal parties to the legal action. The court has the responsibility to protect the well-being of dependent children affected by divorce, which may be straightforward when the parents are in general agreement or hotly contentious when they are in battle. Child

Telegram: @medical_k

www.konkur.in

custody subsumes both legal custody, referring to the responsibility for making major decisions about health and education, and physical custody, referring to which parent is spending time with the child. Many jurisdictions favor awarding joint legal custody to both parents unless there is evidence that this would be frankly detrimental to the child's best interests. Under those circumstances, the court may grant sole legal custody to one parent, with or without time-sharing with the other parent. A determination of the best interests of the child is made by evaluating all of the factors affecting the welfare and interests of the minor child and the circumstances of that family, including, but not limited to: the demonstrated capacity of each parent to facilitate and encourage a close and continuing parent–child relationship and to determine, consider, and act upon the needs of the child as opposed to the needs or desires of the parent; the moral fitness and mental and physical health of the parents; evidence of domestic violence, sexual violence, child abuse, abandonment, or neglect; and the developmental stages and needs of the child and the demonstrated capacity of each parent to meet the child's developmental needs.

Treating psychiatrists of a parent or child in custody or visitation litigation may have important information that could influence the court's ruling. The scope and limits of confidentiality in such matters may become a difficult and contentious question. Further, the availability of the psychiatrist to write reports, testify, or advocate in these adversarial legal proceedings is fraught with conflicting ethical, legal, and therapeutic duties. Many treating psychiatrists have sought to avoid becoming entrapped in these dilemmas by limiting their documentation and recollection, though it may not be possible to predict which patient will be the source of a subpoena. Consultation with an attorney and referral to a forensic psychiatrist may be advisable for the treating psychiatrist confronted with such circumstances.

Child Abuse

Reports of suspected maltreatment, which are mandated by law for health care and school personnel, will trigger investigations by the police or a child protective agency. If probable cause for maltreatment is found, such as bruises or malnutrition, the child can be removed from the home, and the agency might petition the court for alternative placement in foster care. Allegations of sexual abuse usually result in criminal charges against a

Telegram: @medical_k

www.konkur.in

parent, family member, or nonfamilial perpetrator. As the victim of interpersonal violence, children and adolescents suffer enduring psychological injuries, which may also lead to civil court actions seeking to recover compensation for the injured child. Younger children are more vulnerable since, as a rule, they are less able to protect themselves from being exploited by adult predators.

Society and the medical profession have traveled far in the last 100 years from a time when physical child abuse was unrecognized to the current era of far greater sensitivity to multiple forms of maltreatment, including neglect, emotional and physical abuse, and sexual molestation. However, significant difficulties arise in the evaluation of allegations of sexual abuse, especially in young children. The psychiatrist examining a child about whom there is an accusation of sexual abuse must face the challenge of infusing scientific objectivity into the practical task of providing judgments regarding the validity of symptoms, their putative etiology, the harms suffered by the child, the prognosis, and what present and future treatment interventions are indicated.

58.2 Ethics in Psychiatry

LAURA WEISS ROBERTS, M.D., M.A.

Ethics is a scholarly discipline that brings a greater understanding of moral aspects of human experience and action. Psychiatry, more than any other field of medicine, concerns itself with studying and strengthening the capacities that make humans unique and that allow people to attach,

Telegram: @medical_k

www.konkur.in

learn, love, reason, feel, live with one another, and make choices. Separately and together, the fields of ethics and psychiatry examine human meaning, intention, and consequences, and both are concerned with the expanse and limits of the self in the world. Thus, by their natures, ethics and psychiatry are overlapping fields of inquiry.

With so much in common, it is perhaps surprising that the field of psychiatry enjoys more than its share of ethical controversy. Psychiatry is viewed with skepticism by society at large, and the practice of psychiatry presents a number of concerns that can be seen as ethically problematic. Even psychiatrists themselves disagree on matters of ethical importance within the profession. Long-standing ethical issues related to power and intimacy in psychodynamic–psychotherapy relationships are now joined by intriguing new ethical questions about privacy and boundaries in treatment in the modern era of telehealth and smartphone deliverables. Similarly, older dilemmas regarding the potential exploitation of vulnerable individuals in psychiatric research have now been joined by new debates regarding patient autonomy, unconscious bias, and equity in healthcare. Old controversies regarding patient confidentiality in publishing patient case reports are now joined by new uncertainties regarding privacy in technologies that use machine learning or artificial intelligence, for example, to identify individuals who are at risk of suicide based on social media activity. Novel issues pertaining to topics as widely varying as psychiatric genetics, interpersonal violence, sexuality, and global mental health disparities arise each day among the global context of a changing climate, the aftermath of a novel pandemic, and increasing demands for racial justice, highlighting the complex and evolving nature of advancing mental health care.

Learning about ethics is helpful preparation for all physicians, including psychiatrists and psychiatrists-in-training who encounter complex dilemmas in their everyday work. Physicians might begin by familiarizing themselves with relevant ethical guidelines, including those of the American Medical Association (AMA), the American Psychiatric Association (APA), and the American Academy of Child and Adolescent Psychiatry. Historical ethical codes, such as the Hippocratic Oath of the 4th-century BC and Percival's *Medical Ethics* from the late 1800s, shed light on how standards of conduct for physicians have evolved. Psychiatrists must have a sound working knowledge of ethics resources

Telegram: @medical_k

www.konkur.in

from related areas, as well, such as professionalism, legal concerns, gender-related issues, and cultural competencies.

Are general codes of ethics for physicians sufficient for an understanding of the ethical requirements of psychiatrists? Should psychiatrists be held to a higher or different standard of ethics than other physicians? Many psychiatrists argue that a more complete knowledge of ethics is particularly important for mental health practitioners because of the nature of mental disorders and the impact of stigma. Others argue that greater mastery of ethics is essential because of the influence that psychiatrists may have on their patients' lives as a result of transference, the set of emotions and thoughts brought to the therapeutic relationship from the patient's prior life experience. Yet others argue that true ethics expertise, robust decision-making skills, and disciplined ethics practices are of special importance for psychiatrists because of their professional power to initiate involuntary treatment in certain situations. For all of these reasons, psychiatrists and psychiatrists-in-training will ideally possess a thorough understanding of the field of ethics, including its underpinnings and its applications.

Toward this aim, this chapter introduces the foundations of present-day ethics in psychiatry. Outlined are key bioethics principles and illustrations of approaches to identifying and resolving psychiatric ethics dilemmas.

ETHICAL SCHOOLS OF THOUGHT

Several ethical schools of thought have influenced how physicians understand ethical aspects of medical practice. Examples include the deontologic school, utilitarianism, justice-based ethics, virtue-based ethics, and care ethics.

Telegram: @medical_k

www.konkur.in

Table 58.2–1.
Examples of Ethical Models of Thought

Model	Major Figures	Key Features	Strengths	Limitations
Deontology	Immanuel Kant	▶ Absolute good and right exist ▶ Ethical persons fulfill absolute duties unconditionally	▶ Certain obligations (e.g., respect for persons) are nearly universal	▶ Obligation is valued over consequences and relationships
Utilitarianism	John Stewart Mill and Jeremy Bentham	▶ The consequences of actions and rules must be evaluated ▶ Ethical persons fulfill the greatest good for the greatest number of people	▶ Impartially assessing interests is valuable in public policy ▶ Beneficence is one important goal	▶ The minority may be required to sacrifice too much for the sake of the majority ▶ Harm to individuals or groups may be justifiable ▶ This model is difficult to translate into practice
Justice-based ethics	John Rawls	▶ Respect and fairness to each individual are required in decision making	▶ Respect for persons is demonstrated ▶ Equality is one important goal	▶ Clinical decision making is limited to the principle of fairness
Virtue-based ethics	John Gregory and Thomas Percival	▶ Decision making is rooted in individual qualities ▶ An action is ethical if it is what a virtuous person would do	▶ Internal values are more important than external rules ▶ The qualities of the individual are most important	▶ It is possible to act wrongly out of virtue ▶ Virtue may be unclear or pluralistic
Care ethics	Carol Gilligan	▶ Empathy and compassion are valued over prescriptive constructs ▶ All persons are listened to and heard ▶ Relationships are prioritized	▶ Respect for persons is demonstrated ▶ Pragmatic elements of care are given value in decision making	▶ Ambiguity may be difficult to tolerate ▶ Professionals must balance individual preferences with professional obligations, laws, and ethical standards

Reprinted with permission from Laura Weiss Roberts, Dyer AR. *Concise Guide to Ethics in Mental Health Care*. American Psychiatric Publishing; 2004.

These perspectives differ greatly on what constitutes the beliefs and actions of a good person. The philosophers who developed these paradigms sought to explain as much as possible with a few simple rules. Such simplicity is elegant academically, though harder to apply in real life, as Table 58.2–1 notes. Each school of thought, taken alone or taken to an extreme, may lead to conclusions that most people in a pluralistic society would find unacceptable. Nevertheless, these models provide a framework for discerning and evaluating moral issues encountered in everyday experience.

The deontologic school centered on the work of Immanuel Kant (1724 to 1804), who articulated the inherent sacredness of the individual person and the primary intention of a human being as a moral agent. He believed that certain ways of behaving are absolute from an ethical perspective, irrespective of consequences. Kant articulated a rule called the "categorical imperative" guiding all moral behavior. His first formulation of the categorical imperative was that a person should "act only on that maxim through which you can at the same time will that it should become a universal law." For example, in deciding whether to lie or steal or kill, individuals should think about whether they want others to engage universally in these behaviors. Kant's second formulation of the categorical imperative was to "act in such a way that you always treat humanity, whether in your own person or in the person of any other, never

Telegram: @medical_k

www.konkur.in

simply as a means, but always at the same time as an end." In other words, it is unethical to use another person solely as an object to obtain a goal without concern for the effect of one's actions on the person. Moral value, in Kant's system, relates to respect, rationality, and duty in relation to the moral agent.

The utilitarian school of thought originated with Jeremy Bentham (1748 to 1832) and John Stuart Mill (1806 to 1873) in 19th-century England. They argued that the value of an act should be judged solely on its effect or consequences. Acts are ethically right, in this view, if their effect is to produce the greatest good for the greatest number of people. Acts are not right or wrong in and of themselves, according to act-utilitarians. Lying, stealing, and killing are not inherently wrong, for example. In this school, the ends justify the means. Rule-utilitarianism moves beyond act-utilitarianism to suggest that good individuals will undertake decisions guided by rules that—if followed by all people—would bring about the greatest good for the greatest number of individuals. In this formulation, there is more "forgiveness" for decisions with unpredictably negative outcomes. Rule-utilitarianism does not address the role of the intentions of individual moral agents, nor does it answer the question of what is "good."

More recently, in contrast with utilitarianism, John Rawls (1921 to 2002) developed a school of thought drawing from his concept of justice. It followed upon strengths of Kant's deontologic approach in that it highly valued the individual as a moral agent. Rawls supported the rights of the individual as a matter of fairness. He gave primacy to the intrinsic worth of each person rather than to a metric that assessed the greatest utility for the group as a whole. He stated, "Each person possesses an inviolability founded on justice that even the welfare of society as a whole cannot override." Rawls asserted that in deciding what to do and what rules and systems to establish, people should place themselves behind a "veil of ignorance" and assume that they do not know who they are in the system. For example, in deciding what welfare benefits a society should offer and the amount of taxes to impose on the rich, people should assume that they do not know whether they will be rich or poor. In deciding what authority doctors have over patients, people should assume that they do not know whether they will be in the role of the doctor or in the role of the patient. Rawls' approach, as with that of Kant, does not rely on the consequences of actions but, rather, their primary intent.

Telegram: @medical_k

www.konkur.in

Virtue-based theory has contributed greatly to the ethical framework of medicine and the key concepts of professionalism. John Gregory (1724 to 1773) was a Scottish physician–ethicist, and Thomas Percival (1740 to 1804) was an English physician–ethicist. Their work, taken together, created the foundation for the modern ethical concept of medicine as a profession. Concerned about exploitative, self-interested, and entrepreneurial practices of physicians at the time, they articulated the virtues of scientific and clinical competence, dedication to the interests of the patient, and service to the public through ensuring the skills of peers and students or apprentices. Gregory described the moral qualities of an astute and compassionate physician as follows:

> The chief of these is humanity; that sensibility of heart which makes us feel for the distresses of our fellow-creatures, and which, of consequence, incites us in the most powerful manner to relieve them. Sympathy produces an anxious attention to a thousand little circumstances that may tend to relieve the patient; an attention which money can never purchase. . . If the physician possesses gentleness of manners, and a compassionate heart, and what Shakespeare so emphatically calls 'the milk of human kindness,' the patient feels his approach like that of a guardian angel ministering to his relief: while every visit of a physician who is unfeeling, and rough in his manners, makes his heart sink within him. (Gregory, John. *Lectures on the Duties and Qualifications of a Physician*. Carey & Sons; 1817:22,23.)

Gregory and Percival individually emphasized the virtues of the honorable physician as demonstrating self-sacrifice and self-effacement and as seeking at all times to advance the field of medicine, not for financial gain but the benefit of others in society. The modern notion of integrity derives from this line of thought, and the work of Gregory and Percival continues to inform the discussion of conflicts of interest and how they may be avoided or resolved.

Carol Gilligan (born 1936) developed care ethics as a skeptical response to the history of ethical thought, in which concepts of "moral development" elevated predominately by empowered white men were naturalized while historically marginalized voices were excluded, amounting to arbitrary moral indifference. While deontologic, utilitarian, and justice- and virtue-based ethics primarily employ prescriptive ethical constructs, care ethics emphasizes modes of cognition, such as empathy and compassion, and pragmatic elements of care, such as attentiveness, responsiveness, and interdependence, that require epistemic openness, humility, and tolerance of ambiguity. Care ethics affirms a decision-making process in which all individuals are valued according to these ideals.

Telegram: @medical_k

www.konkur.in

These schools of thought have been highly influential in present-day principles of ethics that the AMA and APA advance. Other schools of thought exist in the United States and throughout the world, with rich and long-standing traditions and different implications for current practice. From legal and ethical points of view, physicians engaging in professional activities in the United States are held to the AMA and APA codes of ethics and standards.

BASIC ETHICAL PRINCIPLES

The modern field of biomedical ethics takes a primarily principle-based approach. In their influential text *Principles of Biomedical Ethics,* Beauchamp and Childress defined the most critical principles to be autonomy, beneficence, nonmaleficence, and justice. The Belmont Report on human research ethics elevated the concept of respect for persons, and ethics scholarship has emphasized the principle of respect for the law. Other principles, such as compassion, confidentiality, fidelity, integrity, and veracity, are also central to the practice of psychiatry. See Table 58.2–2. Ethical analyses examine the interplay of these principles and seek to identify and resolve when ethical principles are in conflict.

APPROACHING ETHICAL DILEMMAS

Ethical dilemmas do not typically emerge in simple situations of doing good versus doing bad. In such situations, there is no dilemma. Indeed, ethical dilemmas occur when two seemingly good things are at stake. Consider the example of a psychiatrist who receives a request from a worried and loving mother to provide information about issues arising in her son's therapy sessions. The son has a good relationship with his mother but has been bullied at school, feels embarrassed, and does not want his parents to know what is bothering him. For the psychiatrist, the good of responding empathically and with accurate information to the distressed mother competes with the good of protecting the fragile patient alliance with the son. Dilemmas often come when two or more of the basic bioethics principles are in conflict or cannot be completely fulfilled given the circumstances of a particular situation.

Telegram: @medical_k

www.konkur.in

Table 58.2–2.
Examples of Biomedical Ethics Principles

Autonomy	The notion of self-rule; the capacity to make authentic decisions related to one's body and mind.
Beneficence	Doing good; the commitment to seek to bring about benefit.
Compassion	Deep regard for the experiences and suffering of others.
Confidentiality	A legal privilege associated with the right of privacy; the obligation not to disclose information obtained from a patient or observed or gathered in caring for a patient.
Fidelity	"Faithfulness" or loyalty to ethical ideals.
Integrity	The notion of being whole or complete; the capacity to adhere wholly to the principles of the profession.
Distributive justice	Equitable distribution of benefits and burdens in society.
Nonmaleficence	Avoiding harm or injury to others.
Respect for the law	The obligation to adhere to the law.
Respect for persons	Fundamental regard for the dignity, sacredness, and value of the individual.
Veracity	"Honesty," involving the positive duty to tell the truth and the negative duty to avoid deception.

Recognizing Ethical Issues and Tensions

The ability to identify ethical issues and tensions present in the patient care situation is thus the first and most basic of the ethics skills important to the sound clinical practice of psychiatry. Indeed, it is increasingly appreciated that every aspect of clinical care can have ethical significance. The judgment of a clinician that a patient's characteristics, symptoms, or challenges warrant a psychiatric diagnosis has ethical

Telegram: @medical_k

www.konkur.in

meaning. Moreover, the observation that individuals who belong to underrepresented minority groups are more likely to receive more serious and more stigmatized clinical diagnoses, such as schizophrenia, than individuals who belong to majority groups– despite having the same symptom profiles and clinical histories– reveals the role of bias and potential discrimination in assessment and diagnostic procedures.

Recognizing the ethical features of a patient's case requires sensitivity, and this capacity is enhanced by knowledge of ethical principles and how they may come into conflict.

Seeing how ethical principles may compete or collide is informative and can help practitioners to discern a path forward. For instance, consider the case of a newly diagnosed cancer patient who, overwhelmed and fearful, attempts suicide by overdose. She requests aid in dying from her oncologist, who also feels overwhelmed and fearful because of the patient's reaction, and refers the patient for a psychiatric evaluation. The psychiatrist learns that the patient's mother died from cancer and that she was her mother's only caregiver over the long and difficult course of her illness. The psychiatrist finds that the patient likely had a pre-existing depression before learning of her cancer diagnosis. The patient is decisionally capable, despite her distress, and the psychiatrist feels great empathy for the patient. In this example, many principles are in play, and several are in tension: most clearly, honoring the patient's wish to die (autonomy) conflicts with the physician's responsibility to avoid harm (nonmaleficence). A superficial analysis would suggest that the patient's right, especially in an autonomy-oriented society, would trump all other considerations.

Sound standards for clinical and ethical care are those that are informed by the full set of ethical principles that govern medicine. By recognizing the two principles that are in opposition—in this case, autonomy and nonmaleficence—and considering the other principles at play in the situation, the clinician begins to see additional options for intervention that align with standards of medicine. In this case, identifying ways of reducing the patient's physical and psychological suffering, treating her pre-existing condition, providing accurate information about the nature of her condition and potential treatments, and adhering to state legislation regarding assisted suicide all may contribute to an improved physical and mental health outcome for this patient. Ideally, clinical care and ethical reflection work together, as illustrated in this case.

Telegram: @medical_k

www.konkur.in

The disciplined exercise of identifying ethically salient concerns in a clinical situation and framing and exploring the relevant bioethics principles can help open up the thinking of the clinician. Reflecting on related areas that influence ethical facets of the case, such as considerations regarding the law, the patient's background or identity, and the patient's culture is also valuable. These efforts, taken together, represent an important ethical skill and the initial step in clarifying ethically sound strategies for optimal patient care.

Gathering Additional Information and Expertise

Ethical questions sometimes arise in a clinical situation when there is simply too little information or when clinicians are working at the boundary of their experience or scope of practice. In such situations, additional information or broadened and deepened expertise may lead to a ready resolution of the problems at hand. Data or expert guidance could come from the patient's prior medical records or clinical practice and ethics guidelines. In addition, speaking with an experienced supervisor, seeking advice from a colleague with specialized expertise, requesting ethics or legal consultation, and/or reviewing supplemental clinical data from outside sources may help.

Consultation-liaison psychiatrists see the value of additional data-gathering and consultation as resolving apparent ethical issues frequently in their work. Psychiatric consultation services have long fulfilled an important ethical function in most hospitals. For example, if a patient is declining potentially life-saving care for what appears to be an irrational reason and is demanding to return home against medical advice, a psychiatric evaluation may reveal an underlying condition, such as an addiction, delirium, early dementia, or poor pain control, interfering with the patient's decision making. Once this underlying condition is treated and the symptom burden is lessened, the patient's decisional capacities may improve, leading to what appears to be a more rational decision to the caregiving team. If the patient is not experiencing a threat to their decisional capacity, it is important to explore the patient's values, background, and reasons for making a decision that contrasts with the medical recommendation. Cultural and religious preferences, fears based on past experiences, implicit bias, or issues related to family stresses may be influencing the decision. Seeking additional background information to evaluate these factors may be very helpful in developing health-

Telegram: @medical_k

www.konkur.in

preserving strategies for this patient, such as consulting a religious leader, inviting emotional support from a family member or counselor, or identifying appropriate social service resources. In all of this, the caregiving team is wise also to obtain consultation from the legal service of the hospital. Information on the role of state or federal law in the case will help the physicians to determine whether temporary or long-term guardianship may be appropriate to pursue.

Thus, in approaching an ethically complex clinical situation, recognizing the ethical dimensions of a patient's care and then seeking additional information or expertise are the two initial steps to take in resolving dilemmas and developing ethically astute treatment plans.

Identifying Risky Situations and Arranging for Appropriate Safeguards

Many situations in patient care present predictable ethical challenges, and with experience, astute clinicians begin to anticipate when these ethically risky situations are likely to occur. A clear illustration is when a patient is impulsive, and the caregiving team must ensure the safety of the patient and others, for example, family members or the clinic staff. The clinician may be tempted to make choices that differ from usual clinical practices because of the situational threat. When the patient is a celebrity or an influential person, other ethical risks can enter into the clinical picture. Staff members may be tempted to review the patient's electronic medical record, and caregiving physicians may begin to change their usual clinical practice, consciously or not, in order to please or garner favor with the special patient. A very different example is when there is a need to report child abuse or neglect. In this case, the psychiatrist may feel emotionally conflicted, wanting to abide by the law but feeling worried about the impact of the intervention on the therapeutic alliance with the family or about the impact of the investigation on the child. When entrusted with the care of vulnerable individuals, such as trauma survivors, children, or extremely ill patients, psychiatrists will recognize numerous ethical risks that may arise.

Ethical dilemmas signal the need for additional safeguards in order to ensure that an appropriate standard of care is upheld. Additional safeguards may include incorporating a broader health care team, introducing alternative decision-makers for vulnerable patients who lack decision-making capacity or obtaining permission from the patient to

Telegram: @medical_k

www.konkur.in

engage the family more fully. When a psychiatrist routinely works with high-risk patients, the clinical setting itself must have more safeguards, such as physical safety training for clinical staff. A geriatric psychiatrist who works with many individuals with advanced dementia may need to have a close working relationship with other clinicians, legal advocates, and the court in order to facilitate optimal patient care. In sum, heightened safeguards help address the ethical risk that is associated with psychiatric practice in all settings. When such risk is predictable because of the context or the patient population, ethically astute psychiatrists will build safeguards into their routine practices for the good of the patients and the caregiving team.

Working Within One's Scope of Practice and Engaging in Continuous Learning

Working within one's scope of clinical competence is considered ethically important because of the risk of doing harm when practicing with insufficient expertise to care for a patient properly. If physicians are confronted with patient care situations that are outside of their scope of competence, then referral or, at the very least, consultation and supervision are appropriate. Sometimes physicians practice in settings where referral is not feasible. In rural settings, for example, telehealth services may bring additional expertise to the care of the patient. In training settings, where early-career physicians may lack expertise, close supervision helps to ensure an appropriate standard of care. In emergency situations, clinicians are expected to do their best and not to abandon the patient in extreme need.

Related to the ethical obligation to work within one's areas of competence is the responsibility to continue to learn. This imperative relates to the fundamental concepts of serving the best interest of the patient and avoiding harm in clinical care. Remaining aware of advances in one's field of practice and domains of competence is critical to optimal patient care and ensures that one's practice remains within community standards.

Reflecting on One's Values and Perspectives

Psychiatrists are taught to pay close attention to their responses to a patient, including how they respond to a patient's appearance, emotions, and personal story. Implicit bias greatly shapes interpersonal interactions

Telegram: @medical_k

www.konkur.in

in everyday life and in clinical care. Awareness of potential sources of bias and of countertransference (the set of emotions and thoughts that the psychiatrist brings to the therapeutic relationship from prior experiences) is valuable in clinical care and provides insights into the ethical dimensions of a patient's care. Indeed, to conduct ethically sound patient care, psychiatrists must be able to see how their experiences, attitudes, and feelings influence their perceptions of the ethical aspects of a clinical situation. Awareness of one's reactions may help prevent ethical blind spots and even breaches of ethical conduct. When a psychiatrist finds a patient very attractive or when a patient makes the psychiatrist very uncomfortable or angry, these emotional cues should be seen as clinical and ethical signs that require acknowledgment, clinical interpretation, and a therapeutic response.

Medical professionals are just as susceptible to biased thinking as the general population. Implicit and explicit biases held by health professionals perpetuate health disparities and nonequitable systems of care. A commitment to addressing discrimination and identify and eliminate structural bias through clinician training and other methods is increasingly viewed as a professional value and necessary to uphold ethical principles.

Ideally, team-based care and teaching settings will create opportunities to consider how different team members or supervisors, and trainees view the ethical issues present in a patient care situation. Astute team leaders will facilitate explicit discussion of these issues and guide their colleagues in defining the conflicting ethical principles. Clarifying differences in the points of view of team members may prevent later misunderstandings. Team leaders can demonstrate the importance of speaking with the patient, gathering additional data, working within one's scope, introducing specialized expertise, and building in appropriate safeguards.

DECISION-MAKING STRATEGIES

Jonsen, Siegler, and Winslade created a four-part model for clinical decision making that many health care settings have adopted. The four elements to consider when making a decision include (1) clinical indications, (2) patient preferences, (3) quality of life, and (4) socioeconomic or external factors. In this model, clinical indications have the greatest weight on decision making. Clinical indications refer to the

Telegram: @medical_k

www.konkur.in

physician's obligation to diagnose a patient's condition carefully, to inform and educate the patient about the illness process, to consider the available treatment options in light of appropriate standards of care, to make therapeutic recommendations that adhere to these standards, and to ensure that treatments are provided competently and fulfilled properly in partnership with the patient.

The second element of this decision-making model, patient preferences, is grounded in the principles of respect for persons and autonomy. Once the physician presents the patient with recommendations based on what is clinically indicated, the physician elicits the preferences of the patient. In the practice of psychiatry, the nature of mental disorders may interfere with patients' decisional capacity, voluntarism, or ability to identify or express their preferences. The ethically astute psychiatrist will thoroughly evaluate decisional capacity, keeping in mind that this capacity may change with time and under certain circumstances. When a patient is unable to provide informed consent, appropriate decision-making safeguards, such as an alternative decision-maker, may be put in place in accordance with state law.

Quality of life is the third element in the Jonsen, Siegler, and Winslade model, referring to the sense of personal satisfaction individuals express and/or experience with regard to their physical, mental, and social situations. In assessing quality of life, physicians must directly engage with patients regarding their values and points of view. The physician must not make assumptions about what represents a good life for the patient. Clinical indications and patient preferences are weighted more heavily than quality of life in the decision-making model because, when overweighted or incorrectly assessed, quality of life could be used to justify decisions that do not meet current ethical standards in society.

The fourth element in this clinical decision-making model entails socioeconomic or external factors. These factors are diverse and include the interests of society, the role of family members, cultural factors, and costs and limitations in access to care. This element is last primarily because of the obligations of beneficence. The United States defines denying a patient life-saving treatment in an emergency on the basis of ability to pay as unethical and illegal, for example. In less acute situations, however, a discussion with patients about the costs of care and how these costs may affect their choices of treatment is important and ethically acceptable.

Telegram: @medical_k

www.konkur.in

EXAMPLES OF ETHICAL PRACTICE STANDARDS IN PSYCHIATRY

Several texts and resource documents provide comprehensive overviews of ethical practice standards in psychiatric practice. Key concepts related to several ethical practice standards for psychiatry are briefly outlined below and draw upon the schools of thought, biomedical ethics principles, and the four-part ethical decision-making model described in this chapter.

The Therapeutic Relationship and Professional Boundaries

The therapeutic relationship presupposes that the physician is worthy of the patient's trust. The physician's expertise and the physician's intention to do good, avoid harm, and place the patient's best interest above all other interests are the basis of that trust. Professional boundaries are behaviors that align with these fundamental commitments to serve the wellbeing of the patient.

Interactions with patients fulfill or gratify the interests of the physician rather than the interests of the patient can fracture or destabilize the foundation of trust. One example is the ethical problem of intimate relationships arising between physicians and patients. The APA is explicit in its direction that psychiatrists must not engage in sexual relations with patients, including former patients. Such intimacies are inherently exploitative; they interfere with therapy, risk harm to the patient, and undermine confidence in the profession, thereby damaging the ability of others to benefit from psychiatric care. The profession of psychiatry sees sexual contact during therapy or ending therapy in order to start a relationship as indefensible.

Some have argued that the power differential between a former therapist and patient is the primary reason to forbid relationships between them. Many relationships, however, have power differentials because of the different earning capabilities of the partners, different levels of educational achievement, or a society that gives more power to one gender, one class, or one ethnicity over another. The reason to bar sexual relationships between psychiatrists and present and former patients is more complex than that. The prohibition protects patients from being lured into a relationship that the patient would not otherwise desire because of a genuine need for treatment. The prohibition also helps to ensure that the psychiatrist stays focused on the patient's wellbeing. Self-effacement is an

Telegram: @medical_k

www.konkur.in

important virtue that asks physicians to put away their own needs or wishes for the sake of the patient's health and wellbeing. The modest and self-effacing psychiatrist is willing to forgo relationships with patients outside of standard treatment. The Exploitation Index developed by Epstein helps therapists to identify potentially exploitative practices in the care of their patients.

Therapeutic boundary violations are behaviors that subordinate the interests of the patient to the interests of the physician and are not compatible with the ethical practice of psychiatry. These violations are, by definition, exploitative, although they need not be sexual or romantic. Boundary violations include seeing patients outside of normal office hours or in nonclinical locations, engaging in social or business relationships with patients, accepting gifts from patients, and making nonsexual physical contact with patients. "Friending" or following a patient on social media or completing a Google search for a patient's name are generally considered boundary violations because these actions are likely to serve the interests of the therapist rather than the best interests of the patient. These types of violations carry the potential to take advantage of the patient or to harm the treatment relationship and should therefore be avoided.

Therapeutic boundary crossings are behaviors that are intended to serve the interests of the patient but differ from usual ethical practices. A psychiatrist disclosing personal information to build rapport with a distant and troubled patient or accepting a small handmade gift at the holidays to demonstrate respect for a patient's culture are two examples of boundary crossings.

Traditional views of the boundaries in the therapeutic relationship derive from reflection on long-term, dynamically oriented psychotherapy relationships, typically occurring in urban contexts. Novel questions arise when considering other roles, interventions, and settings. For example, is a child psychiatrist caring for impoverished and traumatized youth in a culturally unique community held to the same expectations as a therapist caring for an older, successful businessperson in a major metropolitan location? Are psychiatrists who see patients once in an emergency department held to the same standard of personal–professional role separation as their ambulatory clinic counterparts? Does a psychiatrist who is consulted about the suitability of a patient with Parkinson disease for neurosurgical intervention establish a therapeutic relationship with the

Telegram: @medical_k

www.konkur.in

patient in the same manner as with a patient needing treatment for depression? Intuitively, these situations require more nuanced responses than strict rules or inflexible codes of ethics. For this reason, medical ethics is understood to evolve by its very nature. This fact does not permit psychiatrists to deviate from expected standards but, rather, permits psychiatrists to apply standards (and, more importantly, their underlying intent) to novel situations.

Confidentiality

The importance of confidentiality in tending to illness dates back to Hippocrates, who said, “What I may see or hear in the course of the treatment or even outside of the treatment in regard to the life of men, which on no account one must spread abroad, I will keep to myself, holding such things.” Confidentiality refers to the physician’s duty to not release information learned in the course of treatment. Salient information may relate to disclosures by the patient, observations of the physician, or laboratory findings, or notes from prior treatment in the medical record. Protection of patient confidentiality fosters the therapeutic alliance and is a prerequisite for patients to be willing to speak freely and openly with their doctors. Table 58.2–3 notes illustrations of optimal practices for protecting confidentiality in psychiatric practice.

Telegram: @medical_k

www.konkur.in

Table 58.2–3.
Examples of Optimal Approaches to Confidentiality in Clinical Practice

- Provide accurate information to patients about the realities of confidentiality in the clinical setting.
- When appropriate, remind patients that the purpose of the medical record is to be shared as a way of providing optimal care by a team of health professionals.
- Openly discuss with patients the legal limitations of confidentiality and avoid assuring patients that their disclosures will be "completely" confidential.
- Do not speak to others or, if working in a team-based care setting, avoid talking with others beyond the health care team, about patients' care without explicit, written permission to do so.
- Actively work within organizations and professional societies to develop state-of-the-art confidentiality safeguards as science, clinical care, health policy, the law, and health care systems evolve.
- Seek consultation and expert guidance when confidentiality safeguard questions arise.
- Model best practices in confidentiality to colleagues, team members, and trainees.

Psychiatric records, including even the identification of a person as a patient, must be protected with particular diligence. A psychiatrist may release confidential information only with the authorization of the patient or when compelled by law. Even when patients have given permission for their personal information to be used, safeguards are still needed. It is important to disclose only that information that is truly necessary for the situation at hand. In teaching and research, one should not unnecessarily release patients' names or identifiable information. Presenters of patient material in ward rounds and case conferences should remind attendees not to repeat what they hear. Confidentiality and the ethical obligation to withhold information endure even after a patient's death.

In an era of electronic health records, digitized medical information, and a push toward national health identifiers, whether, to what degree, and how special privacy protections for mental health treatment will continue to be guarded remains unclear. As patients are increasingly able to access their entire medical record, new issues come to light about the

Telegram: @medical_k

www.konkur.in

extent to which mental health records may receive additional or special safeguards. Although “break the glass” protocols for accessing mental health records are now common, such protocols still allow many different providers access. Mental health providers must remain aware of who has access to the documentation in a patient’s electronic medical record. Transparency of health records has been adopted in many countries. Psychiatrists thus have a responsibility to consider the mental health impact that patients may experience if they access their health records. Psychiatrists may elect to review health record documentation with their patients.

New ethical questions arise every day regarding confidentiality in novel forms of treatment, whether medical or psychosocial. For instance, what are appropriate privacy protections for psychotherapy occurring by telephone, video, Internet, email, or texting? Should health data collected via wellness applications and passive symptom tracking be awarded the same protections and safeguards as data collected in a hospital or clinic setting? How will innovators in clinical research and genetics protect the personal information of specific individuals whose biomarkers, taken together, represent a unique biologic signature?

Informed Consent

Informed consent is an ethical and legal standard that exemplifies the principle of respect for persons and seeks to bring the principle of autonomy to life in clinical medicine. Informed consent is the idea that capable and knowledgeable individuals may freely choose a course of action pertaining to their health. Informed consent can involve accepting a recommended treatment or choosing an alternative, including no treatment (i.e., informed refusal).

Informed consent involves three components: information-sharing, decisional capacity, and voluntarism. With respect to information-sharing, physicians should provide patients accurate and balanced information regarding (1) the nature of their illness or condition; (2) the need for intervention; (3) the anticipated risks or benefits and their relative likelihood, including rare but very serious risks; (4) appropriate alternatives and their attendant risks and benefits; and (5) future consequences of the different choices, to the extent possible. Physicians should offer this information at the level and in a language that the patient understands and, to the extent possible, in an unpressured environment.

Telegram: @medical_k

www.konkur.in

Physicians should build opportunities to clarify points of information and to correct misimpressions into the conversation. Individuals who cannot provide consent must receive information at the level at which they can understand it, and physicians should seek the individuals' acceptance when possible. See Table 58.2–4.

Grisso and Appelbaum characterized decisional capacity as having four subcapacities. The first is the physical and mental ability to communicate. This subcapacity does not refer to the ability to speak a particular language but, rather, the ability to express—including through eye blinks or hand signals—a choice. The second subcapacity is the ability to understand relevant factual information. The third subcapacity is the ability to reason, that is, to weigh the different factors and risks and to think through the choice at hand in an objective and flexible manner. The fourth subcapacity is the ability to appreciate the meaning of the decision and to evaluate the choices in the context of one's life. This capacity is close to the concept of insight, which usually refers to patients' ability to understand the nature and impact of their illness. The capacities should be viewed as a continuum, not simply as present or absent.

Telegram: @medical_k

www.konkur.in

Table 58.2–4.
Examples of Optimal Approaches to Informed Consent in Clinical Practice

- Provide accurate information regarding the nature of the illness and the need for clinical intervention; anticipated risks and benefits of the proposed intervention, including rare but serious risks; alternatives to the proposed treatment and their likely outcomes, including no intervention.
- Avoid using overly complicated language and overwhelming patients with too much technical information.
- Be attentive to patients' comfort, communication style, and interpersonal cues.
- Invite patients to ask questions and double-check their understanding of what was explained.
- Provide additional information if requested by patients.
- Use translators when appropriate and, if desired by patients, include family members in the information-sharing session(s).
- Supplement the information-sharing dialogue with written materials as appropriate.
- Evaluate each of the four components of decisional capacity: capacity to communicate, capacity to understand, capacity to reason, and capacity to appreciate.
- If symptoms or stressors interfere with optimal decision making, seek to ameliorate patients' discomfort to help support their ability to approach the decision process.
- Invite patients to express their preferences.
- Explore the reasons and hopes behind these preferences.
- Provide emotional reassurance and eliminate, to the extent possible, coercive pressures that patients may be feeling.
- Clarify patients' values and patterns of past personal decisions.
- Create a context of nonjudgmental support and open and ongoing communication with patients.

Many psychiatric conditions erode the cognitive strengths that underpin decisional capacities. Patients with severe and persistent mental illness may suffer episodic, fluctuating, or progressive impairments of decisional capacity. Ideally, the informed consent process consists of repeated opportunities over time to gather relevant clinical information and to

Telegram: @medical_k

www.konkur.in

discuss and clarify patients' values, preferences, informational needs, decisional abilities, and decision-making processes. Engaging with consent in a manner that is ongoing and continuous enhances patients' abilities to express greater autonomy, voluntarism, and informed decision making, and more deeply and honestly fulfills the ethical obligations of the physician.

Voluntarism is the capacity that relates to one's ability to act freely, in the absence of coercion, in expressing one's authentic wishes. "Deliberateness, purposefulness of intent, clarity, genuineness, and coherence with prior life decisions" are key elements of the capacity for voluntarism.

Roberts has conceptualized voluntarism as having four cardinal dimensions: (1) developmental factors, (2) illness-related factors, (3) psychological issues and cultural and religious values, and (4) external features and pressures. These four dimensions help to bring additional specificity and nuance to the discussion of autonomy. For example, the voluntariness of an adolescent is understood in clinical practice and in law as less than that of a legal adult except in certain circumstances. Some health conditions render affected individuals as less able to identify (e.g., in relation to alexithymia), to voice (e.g., in relation to mutism), or to enact (e.g., in relation to avolition, amotivation) their personal preferences or decisions. In some cultures, individuals are not encouraged to hold their own distinct and personal choices but instead to subordinate any individual needs to a larger group. And, finally, in some settings, such as institutional, clinical, or legal contexts, individuals may have diminished freedoms or subjectively experience themselves as having diminished freedoms, which affects individual voluntarism.

Informed consent standards are more rigorous for high-risk decisions than for other decisions. This concept is referred to as the "sliding scale" for informed consent. When patients make a choice that may endanger them (e.g., choosing one form of chemotherapy over another), the standard for decisional capacity is higher than when they make a choice that poses minimal or virtually no risk (e.g., having their blood pressure taken). Because declining recommended treatment usually entails heightened risk, the standard for informed refusal also is higher. Physicians must give extra care in providing information and counseling patients regarding alternatives and in verifying decisional and voluntarism

Telegram: @medical_k

www.konkur.in

capacity if a decision under consideration, whether accepting or refusing an intervention, is high risk.

When an individual is not capable of informed consent or refusal, others who are legally authorized may make decisions for the patient. In some cases, the patient may designate the alternative decision-maker. For young children, a parent or guardian may make the decision. At times, a formal legal process must identify a suitable decision-maker. State laws differ in how to identify decision-makers and what direction decision-makers receive, such as whether to make the decision that appears to be in the best interests of the patient or the decision that most closely resembles what the patient would choose if it were possible (i.e., “best interests” vs. “substituted judgment” approaches).

Overlapping Roles and Conflicts of Interest

Differing and overlapping roles are common for professionals who serve society as clinicians and also as teachers, consultants, administrators, and public policy experts. Having more than one role generates ethical questions and often ethical tensions because the duties of each role, by definition, do not align perfectly. (Having more than one role creates dual role, or dual agency, problems.) When roles receive compensation from different sources, issues also arise in relation to competing interests and divided loyalties. Many controversies related to conflicts of interest have become a focus of governmental policy and media reports. Ethically, conflicts of interest matter greatly in that patient needs may be subordinated to the interests of physicians who are motivated by greed rather than serving patient wellbeing. Conflicts of interest occurring at multiple levels—among individual physicians, institutions, and systems of care and research—have eroded public trust in the medical profession.

To illustrate, dual agency conflicts may arise for psychiatrists who work in the military, occupational health programs, or correctional settings. For example, psychiatrists may be called on to use their expertise to make a recommendation on a patient’s fitness for duty, competency to stand trial, or disability. As a result of the evaluation, the patient ultimately may be returned to front-line military or police work or to prison or may receive (or not) financial compensation. The ethical question of what decision serves the best interests of the patient becomes moot in these situations in which the other duties of the psychiatrist, such as protecting the public, become predominant. Particularly vexing dilemmas arise in the correctional

Telegram: @medical_k

www.konkur.in

setting, where psychiatrists may be called on to treat patients against their will when treatment would improve their disorder at the expense of their interests. Psychiatrists may not ethically force treatment on patients to make them competent to be executed. The issue is less clear concerning making patients better able to stand trial when doing so might lead them to spend more time in jail. Honesty, transparency, objectivity, and rigor—always important—are especially salient in the context of dual agency. The key issue to ethical behavior in such situations is to provide accurate information about the nature of the evaluation process, including information about the physician's responsibilities beyond those to the patient and about how usual expectations regarding patient confidentiality are not in force. Before the examination begins, physicians must notify the individuals explicitly about how they will disclose or report the information and conclusions from the evaluation.

Physicians can manage many conflicting roles and conflicts of interest in professional roles through the conscientious use of safeguards such as role separation, recusal, financial limits, responsibility limits, and additional supervision or oversight. Because public trust is at stake in issues of conflict of interest, broad dialogue and scrupulous attention to emerging guidelines and principles are very important for all fields of medicine, including psychiatry. Integrity—namely, intending good, being transparent, adhering to professional standards, and simply behaving in a manner that is worthy of trust—is key. Psychiatrists, moreover, should play an active role in educating the public on the value of professionals participating in broad activities in society, such as research, education, administration, and policymaking, in order to bring the greatest positive value of medical expertise to broader society.

Psychiatric Opinions

In 1964, Barry Goldwater was the Republican candidate for president of the United States. *Fact* magazine sent a questionnaire to U.S. psychiatrists asking whether Goldwater was psychologically fit to serve as president. Despite any direct knowledge of Goldwater derived from an in-person interview, approximately half of the psychiatrists who responded to the survey said he was not fit to serve in the role. The magazine then published an article proclaiming, "1189 Psychiatrists Say Goldwater is Psychologically Unfit to be President." In response, the APA asserted that

Telegram: @medical_k

www.konkur.in

it is unethical to render psychiatric judgments about a person in the media.

It is clearly unethical for psychiatrists to render a definitive psychiatric opinion about someone for whom they have only very limited information or only a biased source of information, such as the media. The practice appears nevertheless to be quite common. Invoking one's expertise as a psychiatrist without full knowledge of a patient is misleading and inappropriate. It is, however, ethical to render an opinion about someone one has not evaluated if one has an adequate source of unbiased information and is prudent in stating the limits of one's knowledge. In fact, psychiatrists commonly render opinions about people they have never met. When senior psychiatrists supervise residents or other mental health practitioners, they render opinions and make suggestions on treatment, although they may not have met the person in question. Psychiatrists are sometimes asked to render an opinion on testamentary capacity—whether someone who is now deceased had the capacity to make an informed decision and whether the person was subject to undue influence. Moreover, esteemed psychiatrists have studied political leaders and historical figures and thereby advanced the understanding of history and human behavior. Similarly, it is ethical for psychiatrists to reanalyze the data of a neutral forensic evaluator and make conclusions about parties they have not interviewed if there is adequate information in the neutral forensic evaluator's report to do so.

Thus, the ethics of rendering an opinion about a person whom one has not examined depends on several factors. Key issues include the purpose of rendering the opinion, the quality of information, and the reason for not interviewing the person.

Responsibilities to Third Parties

Several court rulings have stated that psychiatrists have a responsibility to third parties. These concerns are more properly forensic in nature but are relevant to good ethical practices because of the ethical notion of respect for the law. Court rulings create case law, not ethics. Nevertheless, case law leads to new expectations and indicates society's view of professional responsibilities. Legal rulings also have value because they point ethicists' attention to issues that need deeper consideration. In the original and subsequent *Tarasoff* decisions, for example, the courts upheld the position that psychiatrists must act overtly to protect the community. Courts have

Telegram: @medical_k

www.konkur.in

held psychiatrists liable when their patients, or former patients, have injured or killed people with guns or by reckless driving (e.g., 1983 *Jablonski v. US;* 1988 *Naidu v. Laird;* 1980 *Lipari v. Sears, Roebuck and Co.;* 1983 *Petersen v. Washington*). Subsequent legislative rulings have limited psychiatrists' liability in such matters. Psychiatrists who provide incorrect information place themselves at risk if such action harms the interests of a third party (e.g., *Molien v. Kaiser Foundation Hospitals* and *Ramona v. Isabella*). When clinicians give direct suggestions that affect third parties (such as the advice to get a divorce) rather than helping patients evaluate their choices in the context of their lives, clinicians leave themselves liable for the consequences. The liability is increased if they become directly involved by participating in a confrontation with the third party.

Self-Care and Impairment

Stress, distress, and illness can be occupational hazards of the work of psychiatrists and other physicians. Beyond these concerns, general mental health and wellbeing concerns are increasingly prevalent among medical students, residents, and practicing clinicians, as is the phenomenon of professional "burnout." Burnout has been defined as a syndrome tied to chronic workplace stress involving emotional exhaustion, depersonalization, and lack of personal accomplishment. Extreme stress can cause significant mental health concerns and challenge personal relationships. Health care professionals are also at risk for making errors in patient care when under extreme stress. For these reasons, the imperative to engage in self-care has arisen as a key ethical commitment of health professionals. Individuals who identify as nonmajority, who have greater financial debt, or who are experiencing health problems may also experience greater stress in their professional work. In all of these situations, there can be a "double bind" in which the clinician is responsible for "self-care," and yet the factors that lead to burnout are outside of the control of the individual. For these reasons, self-care alone is not the answer for eliminating stress, distress, and related illness conditions. Greater equity, flexibility, and support in the workplace and in the broader culture of medicine have been identified as constructive approaches that can help diminish the emergence and perpetuation of burnout among health professionals.

Telegram: @medical_k

www.konkur.in

As noted by the AMA's *Principles of Medical Ethics*, professionals have a duty to report colleague misconduct and impairment. Misconduct is defined as professional acts that violate ethical standards, while impairment is the inability to practice medicine due to physical or mental illness or deterioration or the excessive use of addictive substances, such as alcohol. Both may result in harm toward patients, colleagues, or others and should be guarded against, in keeping with the ethical principle of nonmaleficence.

A perceived lapse in professionalism may or may not constitute misconduct, depending on whether or not an ethical standard is violated. Professionalism is a fluid concept informed by cultural and societal mores. Recently, physicians and trainees have drawn attention to the ways in which professionalism is weaponized against individuals who are perceived as being nonmajority or different. For example, women trainees and faculty perceive that more "necessary behavior" is required for them to gain recognition in the workplace. Trainees and physicians of color experience real harm in the form of microaggressions or disciplinary actions when, for example, their dress or appearance is seen as nonconforming to white norms. Professionalism requires rigorous efforts to earn the trust of all stakeholders, including colleagues and patients.

ETHICS AS FUNDAMENTAL TO MEDICAL PROFESSIONALISM

Service to society is the *raison d'être* of the professions. In medicine, physicians provide expertise to advance human health and to lessen the burden of suffering associated with illness. Medical professionals, including those in the field of psychiatry, have the opportunity to develop distinct expertise to help others. These professionals have the responsibility for creating and applying new knowledge, training others, and participating in leadership throughout the profession and broader society. These professionals also have the duty to ensure that colleagues uphold the clinical and ethical standards of their disciplines. Conscientious self-care is increasingly recognized as an ethical responsibility for health professionals, as is vigilance to avoid emotional and physical exhaustion and to address emerging health issues. The role of injustice and inequity in society in health disparities is a central concern of the field of

Telegram: @medical_k

www.konkur.in

psychiatry, especially in light of the potential vulnerability of people living with mental illness.

58.3 Correctional Psychiatry

Arya Shah, M.D., and Jhilam Biswas, M.D.

Correctional psychiatry functions at the boundaries of law and medicine and requires an understanding of ethics and the myriad ways that law impacts the practice of psychiatry. As a subset of forensic psychiatry, correctional work requires being aware of issues of ethics and morality and can be fraught with potential bias and conflicts of interest. Given a large portion of the psychiatric population interacts with correctional settings, psychiatrists benefit greatly from learning about how corrections and law enforcement engage with inmates.

Today, certain county jails in large cities are considered the largest psychiatric hospitals in the United States. Multiple factors, including legal, social, fiscal/health care reimbursement, and political, over the past 70

Telegram: @medical_k

www.konkur.in

years have led to the current substantial presence of psychiatric and substance use disorders seen within American jails and prisons.

Some examples of these factors include reducing beds at state inpatient facilities, “zero tolerance” arrest, sentencing policies as part of the “war on drugs,” and the deinstitutionalization of many individuals with chronic and persistent mental illness without adequate community resources. The unintended consequence of these national policies is that it has criminalized mental illness.

Mental and substance-related disorders, as well as chronic medical conditions, are prevalent public health problems affecting individuals in U.S. correctional facilities, and these settings have become the default mental health system for high-risk populations. The sheer number of inmates with severe psychiatric disorders in the U.S. prison system and the “revolving door phenomena” in which many mentally ill people move continuously between homelessness and the criminal justice system represents a national public health crisis. This risk of reincarceration also exists among prisoners with co-occurring severe mental illness and substance use disorders.

In the postpandemic era, equitable health care among races is a key area of correctional psychiatry and must be addressed in the treatment, research, and advocacy of this patient population. Incarceration disproportionately affects Black Americans, and the data shows that living in a predominantly brown and black community heightens the risk a person will interact with law enforcement and corrections. Providing high-quality mental health care in corrections may be one way to address the inequities faced by disenfranchised minorities and a core area of criminal justice reform.

Over the course of the last decade, the imprisoned population has slowly come down from its height in 2010, but data shows the United States continues to hold a quarter of the world’s incarcerated population. The COVID-19 pandemic did cause a drop in incarceration rates from 2.1 to 1.8 million. While this has been a positive development, many argue the high reincarceration rate will again increase numbers if policies stay the same. Among the incarcerated population, around 20%, or an estimated 356,000, have a severe and persistent mental illness, that is, carry a diagnosis of a serious mental disorder such as schizophrenia, bipolar disorder, or severe depression.

Telegram: @medical_k

www.konkur.in

Notably, not all correctional settings are the same, and there are many types. These include lockups, jails, state and federal prisons, U.S. Immigration and Customs Enforcement (ICE) detention centers, Bureau of Indian Affairs detention centers, U.S. military prisons, jails, and detention centers. There have been recent concerns regarding access to care and other medicolegal issues for persons with severe mental illness in the U.S. ICE system, which is discussed elsewhere in the literature.

The most common correctional settings for adults are jails and prisons. Jails are city- or county-operated correctional facilities that confine individuals involved in the criminal justice system who are awaiting trial or serving short sentences for misdemeanors. There are approximately 3,500 jails in the United States. Detention refers to the period following arrest in which an individual is held in secure custody prior to or after court proceedings. The amount of time a person is in jail varies (e.g., hours, days, weeks, typically 1 year or less). Some individuals may remain in jail for years for more serious charges while awaiting legal disposition of their case, or they may serve their sentence in a jail setting. There is significant variability in size, with some small rural jails holding 10 to 50 detainees and some major metropolitan jails holding 7,500 to 10,000 detainees.

A prison is a facility operated under the auspices of a state or federal government for the confinement of adults convicted of a felony whose sentences generally exceed 2 years. Individuals in prisons may be serving one or more life sentences, and some states have the death penalty. There are approximately 1,300 state and federal prisons in the United States.

Similar to adults, youth in juvenile justice settings face significant mental and co-occurring substance-related disorders, which represent a serious public health concern, and the need for services in the juvenile justice system is high. While involved with the juvenile justice system and family courts, youth may be housed within juvenile detention centers, reception or diagnostic centers, community-based or other residential treatment programs, or juvenile correctional facilities. Some juveniles may be held in county jails, and some youth may be transferred/sentenced to adult prison settings. In many states, certain felony offenses committed by adolescents are moved to adult criminal court. This practice has led to an increase in the detention and incarceration of younger offenders in adult jails and prisons. Data reflect rates of SMI among incarcerated adolescents that are substantially above those found in the community.

www.konkur.in

This chapter will present an overview of American correctional systems and provide background on the demographic and mental health landscape of the correctional population. The chapter will identify ongoing practical, legal, and ethical challenges that a psychiatrist may face while providing care in correctional settings. Finally, the chapter will also aim to make recommendations for psychiatric assessment and treatment in the correctional setting, discuss the roles of mental health clinicians in corrections, and identify phenomena that might influence the future of correctional psychiatric practice in the United States.

PSYCHIATRIC PATIENTS IN CORRECTIONAL FACILITIES

Mental Illness in the Correctional System

The importance of demographic studies of psychiatric disorders in correctional facilities cannot be overemphasized. For advocacy purposes and for public health considerations, the results of this research dramatically portray the critical need for psychiatric services in jails and prisons.

However, the true incidence and prevalence of psychiatric disorders in correctional facilities are difficult to obtain. Well-designed, carefully done epidemiologic studies are costly and complex to carry out, and because of the high inmate turnover rates, doing a point prevalence study of mental illness in jails is difficult. The best way to detect the incidence and prevalence of psychiatric problems in jails is to find cases on admission. Prison inmates stay for longer terms, and conducting a point-prevalence epidemiologic study of mental illness in this setting is more feasible. Despite these difficulties and limitations, the epidemiology of mental illness in correctional facilities is gradually becoming known. In a 2017 special report on mental health problems in prisoners and jail inmates, the Bureau of Justice Statistics estimated that 37% of prisoners and 44% of inmates had been diagnosed with a mental illness by a mental health professional. In general, most authorities now estimate that about 20% to 40% of the correctional population has serious and persistent mental illnesses. In 2010, the Treatment Advocacy center issued a report identifying that jails and prisons housed more than three times as many individuals with serious mental illness than did hospitals. Thus, in 2012,

Telegram: @medical_k

www.konkur.in

more than 350,000 seriously mentally ill offenders were incarcerated in the nation's jails and prisons. (This is contrasted to an estimated 35,000 patients in state psychiatric hospitals.)

FIGURE 58.3–1. Serious mental disorders among the general population and among jail admissions.

Jails. With regard to jails, the few available epidemiologic jail studies highlight that after controlling for demographic differences between jail samples and the epidemiologic catchment area (ECA) samples, jail prevalence rates of mental illness are two to three times higher than those in the general population (Fig. 58.3–1).

Prisons. Because prison inmates stay for longer terms, there are more prison population-based epidemiologic studies of mental illness than there are in jails. The ECA study found that 6.7% of inmates in prisons had experienced schizophrenia at some point, compared to 1.4% of the U.S. household population. A number of studies reveal that, at any given time, a little more than 2% of the inmate prison population is in inpatient or residential psychiatric care.

More than 30% of male inmates and 78% of female inmates with mental illness reported prior physical or sexual abuse, and inmates with mental

Telegram: @medical_k

www.konkur.in

illness in correctional facilities are more likely than other offenders to have a higher prevalence of homelessness, unemployment, alcohol and drug abuse, and physical and sexual abuse before their current incarceration.

HISTORY OF CORRECTIONAL PSYCHIATRY IN THE UNITED STATES

Until recently, the judicial system maintained a “hands-off” policy with regard to conditions in jails and prisons, a doctrine that regarded the inner workings of correctional facilities as beyond the responsibility and authority of the courts and best left to correctional professionals.

It was during the 1970s, during the tidal wave of the civil rights movement, that various studies and court cases exposed the abominable conditions of health and mental health care in the jails and prisons of the United States. These findings led to significant reform of the correctional system and of correctional psychiatry and health care. The confluence of a number of interrelated forces spearheaded this reform, including professional organizational advocacy by the American Medical Association (AMA) and the American Psychiatric Association (APA), “conditions of confinement” lawsuits, which were now entertained by the courts, and the development of standards and guidelines for health and mental health care in jails and prisons.

Telegram: @medical_k

www.konkur.in

Table 58.3–1.
American Psychiatric Association Position Statement on Psychiatric Services in Adult Correctional Institutions (2021)

The American Psychiatric Association Position on mental health services for individuals in adult incarcerated settings should minimally include:

1. Timely and effective access to mental health services screening, evaluation, and treatment, including an appropriate range of therapeutic interventions.
2. Necessary staffing levels to ensure access to care and to provide appropriate services.
3. Quality assurance and improvement reviews to identify and resolve inadequacies of care.
4. As therapeutic an environment as possible, optimized by support, guidance, and advocacy from mental health leadership and collaboration with correctional leadership. Mental health administration should be incorporated into the overall management of the facility.
5. Proper procedures, based on appropriate legal guidance, and staffing to safely administer involuntary medications when clinically indicated and when reasonable attempts at voluntary engagement in medication adherence have not been successful. This should not preclude psychiatric hospitalization if available and clinically indicated.
6. A balance and an effective partnership between security and treatment needs to ensure the effective delivery of mental health services.

Reprinted with permission from the Position Statement on Psychiatric Services in Adult Correctional Facilities (Approved by the Board of Trustees, December 2021). American Psychiatric Association. All Rights Reserved.

In 1974, the AMA carried out a survey of sheriffs administering local jails, which revealed that, in addition to frequently lacking mental health screening and testing resources, fewer than 20% of jails had facilities for caring for individuals with alcohol use disorder, only 10% had any facilities for inmates with drug addiction, and only 14% had facilities for inmates with mental illness. Studies of prison correctional health care revealed that prison correctional health care was no better than that in jails. The APA subsequently published a Position Statement on providing psychiatric

Telegram: @medical_k

www.konkur.in

care in correctional settings, which was prepared by the APA Committee on Psychiatry and the Law, with the most recent version published in 2018 (Table 58.3–1). In 1975, the Federal Law Enforcement Assistance Administration (LEAA) provided a grant to the AMA to upgrade correctional health care. The purpose of the grant was to develop a model correctional health care system and to distribute information on correctional health care issues. Another important goal was the development of a national accreditation program with correctional health care standards. In 1977, the AMA published its first jail correctional health standards; 16 jails were accredited for compliance that year. In 1979, the prison and juvenile correctional health care standards were published.

At the same time, the judicial system was establishing the unique legal context of psychiatric services in jails and prisons—that such services are constitutionally guaranteed. In 1976, the U.S. Supreme Court, in the case of *Estelle v. Gamble*, held it unconstitutional for prison officials to be deliberately indifferent to the serious medical needs of those in their custody, and in 1977, a federal court, in the case of *Bowring v. Godwin*, extended this requirement to psychiatric care.

In 1983, as an outgrowth of the LEAA-funded AMA program, the National Commission on Correctional Health Care (NCCHC) was established. The NCCHC consists of 37 professional organizations, including the AMA and the APA. It assists correctional institutions in upgrading their correctional health care services and, most importantly, has established correctional health care standards and correctional health care accreditation processes. These standards, which are revised regularly, represent the state of the art for correctional health care, and with their recently revised 2018 publication of the NCCHC's Standards for Mental Health Services in Correctional Facilities, the state of the art, as well as evidence-based practice, for mental health services in jails and prisons.

In 1989, the APA published Psychiatric Services in Jails and Prisons. This document, referred to as the APA Guidelines, was developed by correctional psychiatrists for correctional psychiatrists and described in detail the principles governing the delivery of psychiatric services in jails and prisons; the specific requirements for an adequate process of screening, evaluation, and treatment; the specific roles of the correctional psychiatrists; and the application of the principles and guidelines to specific populations. The second edition of the APA Guidelines was

Telegram: @medical_k

www.konkur.in

published in 2000; the third edition, now titled *Psychiatric Services in Correctional Facilities*, was published in 2016.

PERSISTING CHALLENGES IN CORRECTIONAL PSYCHIATRY

Despite the significant burden of psychiatric needs in correctional settings, there exist significant gaps and shortcomings in care within jails and prisons.

Shortage of Correctional Psychiatrists

The National Health Service Core (NHSC) maintains a database of correctional institutions that are designated Health Professional Shortage Area (HPSA) facilities that have a minimum of 250 inmates and a ratio of psychiatrists to inmates of at least 1:2,000. More than 450 correctional facilities nationally have been found to meet the criteria for Health Professional shortages in the database, with such figures likely representing an underestimate of the true count of correctional facilities with a shortage in psychiatric providers. Consequences of such gaps in care have been called to public attention; in the more recent landmark case of *Brown v Plata,* the Supreme Court recognized that as many as 72% of suicides in correctional settings likely related to inadequacies in mental health care, with wait time for receiving care as long as 12 months (Supreme Court Ruling 536, 2011).

The lack of adequate numbers of clinicians in correctional settings may be related to multiple factors. Currently, forensic exposure is sporadic in residency training. This lack of exposure to psychiatric practice in corrections can result in graduates feeling ill-equipped to practice in forensic settings. Furthermore, misconceptions related to justice-involved individuals receiving treatment, apprehension regarding provider safety, and belief that clinical care may be less fulfilling in correctional settings may all contribute to the lack of psychiatric clinicians choosing to build careers in the field. Exposure to forensic psychiatry in training has been proposed as a solution for countering ambivalence and increasing provider comfort with providing care in these settings.

Overcrowding

Telegram: @medical_k

www.konkur.in

In 2006, more than 7.2 million people were on probation, in jail or prison, or on parole. At year-end 2006, this represented 3.2% of all U.S. adult residents or one in every 31 adults. State and federal prison authorities had jurisdiction over 1,570,861 inmates at year-end 2006: 1,377,815 in State jurisdiction and 193,046 in Federal jurisdiction. Local jails held 766,010 persons awaiting trial or serving a sentence at year-end 2006. An additional 60,222 persons under jail supervision were serving their sentence in the community.

FIGURE 58.3–2. Adult correctional populations from 1980 to 2004.

The overcrowding that has resulted from the increase in the correctional population over the last three decades has made many large jails, such as the Cook County Jail in Chicago, the Los Angeles County Jail, and Harris County Jail in Houston, Texas, the country's largest mental institutions (Fig. 58.3–2).

Multiple historical factors have contributed to the current problem of overcrowding and over-representation of mental illness in our county's jails and prisons. With the discovery of chlorpromazine and its antipsychotic properties, there was growing optimism about the possibility of community-based care for individuals with serious mental illness who had previously been institutionalized. The phenomenon of deinstitutionalization in the 1960s involved the closure of state hospitals in hopes of transitioning psychiatric care into community-based mental health treatment programs. However, a variety of social, financial, and legislative factors ultimately contributed to inadequate funding of

Telegram: @medical_k

www.konkur.in

community mental health treatment centers, resulting in a system that was ill-equipped to manage the mental health needs of individuals requiring access to care. The combination of untreated mental illness and lack of access to care in the community have since contributed to the described "revolving door" of incarceration faced by many individuals with mental illness, contributing to the phenomena of "transinstitutionalization" and the over-representation of mental illness within our country's justice system (Fig. 58.3–3).

The Criminalization of the Mentally Ill

Some of the factors contributing to the high rates of people with serious mental illness in the criminal justice system include, as reasons for the increased entry, the process of deinstitutionalization and its accompanying phenomenon of "transinstitutionalization," the inadequate access to the seriously and persistently mentally ill to community treatment, the fact that these patients are arrested at disproportionately higher rates and often have co-occurring substance-related disorders, the prejudice that the mentally ill are more violent than other persons, and the use of jails and prisons as housing of last resort.

FIGURE 58.3–3. Transinstitutionalization from 1950 to 2000.

Telegram: @medical_k

www.konkur.in

FIGURE 58.3–4. Jail incarceration rates by race and ethnicity, 1990 to 2006.

There are additional problems with discharge planning and reentry into the community, including the fact that these patients spend long periods of time incarcerated, the pathogenic nature of incarcerated environments, the lower rates of parole, and the higher rates of recidivism due to inadequate community mental health services.

The United States has the largest percentage of its population incarcerated than any other country in the world. Since 1989, the National Drug Control Strategy, which called for a mandatory minimum sentence for drug crimes, caused the jail and prison populations to grow at a rapid rate. In 1985, the percentage of sentenced drug offenders was approximately 13%. Currently, it is more than 30%. The importance of the relationship between the increase in the number of inmates incarcerated for drug offenses and the disproportionate increases in the numbers of female, nonwhite, and foreign-born inmates cannot be overstated.

Racial Inequity

In addition to the well-recognized phenomenon of mental illness being over-represented in the correctional system, racial disparities among individuals housed in jails and prisons have been viewed as evidence of significant care inequity (Fig. 58.3–4).

While the presence of mental illness alone is a risk factor for justice involvement and incarceration, disparities in access to community treatment may contribute to additional racial inequities. A report from the Office of the Surgeon General identified that racial and ethnic minorities not only have less access to community mental health treatment than do white individuals but that even when received, the care is of poor quality. It

Telegram: @medical_k

www.konkur.in

is possible that such disparities in the community influence the disproportionate number of people of color in the correctional system. Despite making up 13% of the general population, African Americans make up 40% of individuals who are currently incarcerated. Furthermore, there is evidence that individuals of color may be less likely to receive mental health treatment within jails and prisons, with mental health symptoms more likely to be viewed as criminal and to be met with punitive action. Such phenomena highlight the importance of the continued study of structural barriers to equitable access to treatment and enhanced recognition and treatment of mental illness in populations who have historically had inequitable access to care.

THE LEGAL AND ETHICAL PRINCIPLES UNDERLYING THE PRACTICE OF CORRECTIONAL PSYCHIATRY

Landmark Cases in Correctional Psychiatry

In the 1970s, the crucial years of the reform of the correctional system, a series of court decisions established the principle that psychiatric services in the jails and prisons of the United States are constitutionally guaranteed. This legal doctrine holds that under the Eighth Amendment of the U.S. Constitution, which prohibits “cruel and unusual punishment,” whenever a state or the federal governmental entity takes custody of a person, it must provide for the necessities of life that the person otherwise is unable to obtain. These include food, clothing, shelter, and medical care, which include psychiatric care.

In 1976, the Supreme Court, in the case of *Estelle v. Gamble*, held it unconstitutional for prison officials to be deliberately indifferent to the serious medical needs of those in their custody, and in 1977, the federal court case of *Bowring v. Godwin* extended this requirement to psychiatric care. In 1980, another federal court case, *Ruiz v. Estelle*, listed a number of specific components of mental health care components that are required in correctional facilities, including but not limited to the involvement of trained mental health professionals, utilization of systematic screening and evaluation, adequate monitoring of methods and amounts of medications administered, maintenance of a confidential medical record, and implementation of a suicide prevention program.

Telegram: @medical_k

www.konkur.in

In 1989, the case of *Langley v. Coughlin* listed a number of other specific criteria that, if not met, could provide a basis for successful inmate legal claims. Many of these criteria explicitly required providing for so-called secondary or supportive rights, such as taking psychiatric histories and maintaining medical records, in recognition of the fact that such rights are required to facilitate the primary right to diagnosis and actual care. *Langley v. Coughlin* also explicitly requires that care not be limited to psychotropic medication.

Madrid v. Gomez, in 1995, a State of California Department of Corrections legal case, added several factors that may determine the constitutionality of a correctional mental health system. These included that inmates should be able to communicate needs to medical staff, have access to individualized treatment, and reserve the right to a hearing and procedural protections prior to involuntary treatment; furthermore, institutions were required to implement symptoms of quality assurance and hire staff that are competent and trained in the needs of those with mental illness within the correctional system.

In addition to these constitutional mandates, jail and prison mental health services may be required to meet other legal requirements, such as those associated with federal laws (such as the Americans with Disabilities Act), state laws, and other regulations related to liability for medical malpractice.

Mental health in correctional facilities is considered a constitutional guarantee. A lack of it is considered a violation of the Eighth Amendment of cruel and unusual punishment as determined by *Estelle v. Gamble*. However, substance use is variably included as part of mental health and often depends on local courts and governments. The position of the courts has been that the provision of care and treatment in cases of substance use disorder (e.g., for drug abuse) in jails and prisons is not considered an aspect of psychiatric care and, therefore, is not considered constitutionally required. However, there is such an obvious need for the treatment of substance use disorders in jails and prisons that it is usually included in correctional programs.

Ethical Considerations of Correctional Psychiatry

Correctional mental health providers should follow the standards of professional ethics as set out in the APA's Annotations Especially Applicable to Psychiatry to the AMA's Principles of Medical Ethics.

Telegram: @medical_k

www.konkur.in

Although the Preamble to the AMA's Principles states, "A physician must recognize responsibility to patients first and foremost," it then adds the words "as well as to society." Correctional psychiatric practice presents unique challenges related to how the psychiatrist's duties to the patient may clash with their duties to the department of correction, which can be regarded as an aspect of the correctional psychiatrist's duties to "society."

Ethical conflicts may manifest in various features of mental health care in correctional settings. In the correctional setting, there is a conflict between the two distinct roles of the correctional psychiatrist: As the inmate's treating physician and as an employee and agent of a local, state, or private correctional agency. This problem is known as that of "dual loyalty" (also called the "the double-agent problem"). Therefore, while the concepts of autonomy and nonmaleficence are central tenants to the practice of medicine, both of these values may be at odds with correctional perspectives and policies, and the correctional environment might threaten to coerce professional judgment and actions into meeting security needs rather than the mental health needs of individual inmates. Such conflicts can affect the doctor–patient relationship, and the unique power dynamics existing within the correctional setting necessitate that mental health providers consistently monitor unintended identification with correctional authorities and countertransference with inmates. The APA has set forth in its guidelines that the inherently coercive settings of jails and prisons might create additional difficulties for the correctional psychiatrist in regard to obtaining informed consent. It is interesting to note that one legal case stated that it is impossible to obtain true informed consent in this setting.

Confidentiality also presents unique considerations in the correctional setting. Although the usual principles of psychiatric confidentiality apply to the delivery of psychiatric services in jails and prisons, there are special needs presented by these settings, especially in relation to security and safety. The APA Guidelines state, "The rights of the patient to . . . confidentiality must be weighed against the needs of other inmates as well as the institutional needs of safety and security." Furthermore, the limitations of privacy in correctional settings have been acknowledged, given the unique organizational structure within the facility. While the NCCHC Standard on "Privacy of Care" in corrections requires that "mental health services are conducted in private and carried out in a manner designed to encourage the patient's subsequent use of services . . . in

Telegram: @medical_k

www.konkur.in

private, without being observed or overheard by staff or inmates," the standard goes on to acknowledge the limits of privacy with imminent risk is of concern, as well as acknowledging that "in corrections mental health triage commonly occurs at cell-side. As the triage discussion becomes more involved than a simple triage, the clinician should be aware of the need to maintain privacy and move the patient to a clinical setting."

It is critical for psychiatrists and other mental health staff working in correctional settings to define and maintain their role as a clinician, working in the best interests of the patient, as opposed to a forensic evaluator, or as an agent of the court, law enforcement, or of the state or local jurisdiction. Without a release of information, treating psychiatrists should avoid verbal or written communication with attorneys and other court personnel, and they should avoid inappropriate communication with the media. It is also recommended that correctional psychiatrists specify clearly any limits on the usual precepts of confidentiality before initiating treatment, except in emergencies. However, this notice may be presented to the inmate in general terms, such as applying to situations in which the patient or the institution may be at risk.

On the contrary, the correctional psychiatrist must be able to share relevant confidential information with facility administrators (on a "need-to-know" basis) when it relates to the medical management of a patient, security issues, or a patient's ability to participate in programs. Similarly, it is appropriate that there be communication with nonclinical staff regarding an inmate's significant mental health needs that must be considered in classification decisions to preserve the health and safety of that inmate, other inmates, or staff.

The correctional psychiatrist should be sensitive to the fact that confidentiality is especially important to those for whom the lack of confidentiality might have serious legal and other consequences, such as those detainees with pending legal charges. Some practical suggestions for psychiatrists and other mental health staff might include the avoidance of exploration into the details or circumstances of the alleged criminal act(s) and the individual's state of mind, criminal intent, mitigating factors, or other defense strategies. Similarly, at risk are those who have experienced sexual violence, sex offenders, or persons with HIV/acquired immunodeficiency syndrome (AIDS).

Collecting Forensic Psychiatry Information in a Jail or Prison

Telegram: @medical_k

www.konkur.in

The collection and use of forensic information by the correctional psychiatrist present a unique clinical and ethical challenge for mental health clinicians in this setting. The APA Guidelines set out the "distinction [that] must be drawn between information obtained by a correctional psychiatrist in the course of treatment, and information obtained from the inmate in the course of an evaluation for non-treatment purposes."

When correctional authorities ask correctional psychiatrists to collect information for forensic purposes, the NCCHC standards support the refusal of the correctional psychiatrist to do evaluations of inmates for use in adversarial proceedings or to order blood tests to determine drug or alcohol use (unless it is for clinical reasons). These matters are of such concern to the NCCHC that it has promulgated an explicit standard prohibiting health care workers from collecting "forensic information." The standard on Forensic Information in the Standards for Mental Health Services in Correctional Facilities states, "Mental health staff are prohibited from participating in the collection of forensic information," which is defined as "physical or psychological data collected from an inmate that may be used against him or her in disciplinary or legal proceedings." The intent of the standard is to ensure the preservation of the treatment relationship between the provider and the patient.

The NCCHC standard goes on to state that "where state laws and regulations require that such acts be performed by health/mental health staff, the services of outside providers or someone on the institution's staff who is not in a therapeutic relationship with the inmate is obtained." Relevant also are the Ethics Guidelines for the Practice of Forensic Psychiatry of the American Academy of Psychiatry and the Law (AAPL), which deal with this issue explicitly, noting, "When a patient is involved in parole, probation, conditional release, or in other custodial or mandatory settings, psychiatrists should be clear about limitations on confidentiality in the treatment relationship and ensure that these limitations are communicated to the patient."

PSYCHIATRIC TREATMENT IN JAILS AND PRISONS

The Policy Goal of Psychiatric Treatment in Jails and Prisons

According to the APA Psychiatric Services in Correctional Facilities (Third Edition):

Telegram: @medical_k

www.konkur.in

The fundamental policy goal for correctional mental health care is to provide the same quality of mental health services to each patient in the criminal justice system that should be available in the community. This policy goal is deliberately higher than the "community standard" that is called for in various legal contexts, because resource restrictions on community care can sometimes limit the adequacy of available services. Correctional systems provide additional challenges not present in the community, given that incarcerated persons have no options for care other than what is provided in the correctional facility.

The Purposes of Psychiatric Treatment in Jails and Prisons

Psychiatric disorders and psychiatric comorbidities are overrepresented in correctional populations compared with the general population. Correctional facilities and systems are, therefore, legally obligated to address the medical and mental health care needs of individuals in their placement. The purposes of psychiatric treatment in jails and prisons as set out by the APA Guidelines are listed in Table 58.3–2. These principles are echoed in the NCCHC Standards, which add that the goal is the "best level of functioning" and "In the correctional setting, as in most other environments, the immediate objective of mental health treatment is to alleviate symptoms of serious mental disorders and prevent relapses to sustain patients' ability to function safely in their environment."

Models of Health Care in Jails and Prisons

Different correctional settings have different organizational models for health care delivery, and it is important that correctional psychiatrists become familiar with the model that their institutions follow. In many facilities, medical services and mental health services may be under the same or under separate authorities with different administrators and lines of reporting and supervision. Variations include situations in which the correctional psychiatrist is a full-time or part-time state, federal, or county employee, employed by a university or private health care system, or is a locums tenens, part-time or temporary individual contractor providing mental health services to any of the above or alternatively an employee or individual contractor for a national for-profit organization that is responsible for medical and/or mental health care services.

Telegram: @medical_k

www.konkur.in

Table 58.3–2.
The American Psychiatric Association Guidelines on Purposes of Psychiatric Treatment in Jails and Prisons

To relieve the unnecessary extremes of human suffering
To make the correctional facility safer for everyone who lives, works, or visits there
To enable patients to avail themselves of the rights of due process
To permit inmates the opportunity to make use of programs offered
Correctional settings is public psychiatry as jails are the new psychiatric hospitals

Jails and prisons differ in the scope of mental health services that are provided. Jails process most detainees who have a short length of stay, and, accordingly, jails are primarily concerned with the stabilization and management of acute conditions such as acute psychosis, substance intoxication, withdrawal, and suicide prevention. While a person is in jail, the purpose of mental health treatment is to prioritize the detainee's health and safety, but, when appropriate, this might also include the goal and outcome of restored competency to be arraigned or restored competency to stand trial so that their pending legal proceedings may resume. Because this is a forensic and nonclinical role, typically, jail psychiatry staff are not involved in the assessment of whether an individual is competent or is not competent to stand trial. Similarly, they are typically not involved in the treatment of restoration of competency to stand trial, but this may vary by location (and whether the jail has a competency restoration program on-site or if this is a separate on or off-site program). Of course, once an individual returns to jail, ensuring continuity of care and the psychotropic medications (typically initiated in the state hospital or competency restoration program) and other treatments is essential and can be very challenging.

In a prison setting, the outcome might be to return the inmate to the general population with the ability to participate in prison programs, including clinically indicated mental health programs, psychotropic medication administration, monitoring, further psychiatric evaluation and treatment, and preparation for release. Prisons should be considered communities in which individuals spend many years of their lives. As such, prisons need a greater range of services that emphasize long-term

Telegram: @medical_k

www.konkur.in

support for particularly vulnerable individuals, including sheltered and/or residential units (for individuals with stable conditions who cannot be placed into the general population), case management, individual and/or group therapies, and other in-cell programming materials (self-study materials and the like). Programs should be available to prison inmates who repeatedly self-injure, mutilate, those with the need for frequent/repeated psychiatric hospitalizations who might require step-down programming, followed by sheltered or residential unit placement with other similar offender patients, and more intensive treatment to ensure medication compliance, monitoring of their activities of daily living (ADLs), and medication and illness teaching and education, than that which is typically available within general population settings. Sheltered housing and tailored assessment and treatment programs for individuals with developmental disabilities are also necessary.

Issues in Administration and Management

WRITTEN POLICIES AND PROCEDURES. Mental health administrative personnel in a jail or prison should establish written policies on such critical issues as (1) staffing patterns, (2) admission, (3) referral, (4) discharge criteria, (5) health care information management, and (6) interagency and intra-agency communications, especially with regard to confidential medical and mental health information.

THE FACILITY INFORMATION TECHNOLOGY SYSTEM: NEEDS ASSESSMENT AND ALLOCATION OF RESOURCES. With regard to a correctional facility's information technology system, the APA Guidelines point to a capacity for "needs assessment" and state: "It is critical that the administration of the correctional facility have the capacity to gather and assess information relevant to the prevalence of mental illness in the facility because this data forms the basis of the needs assessment that assures an adequate level of care."

THE FACILITY QUALITY ASSURANCE PLAN. One important aspect of the reform of the correctional mental health system calls for each jail or prison to have a quality assurance plan that systematically reviews the quality of mental health services and the efficiency and effectiveness of the utilization of staff and resources in the delivery of services.

Telegram: @medical_k

www.konkur.in

ACCREDITATION AND STANDARDS. The NCCHC has become the major organization establishing correctional health care standards and providing correctional health care accreditation. In 2007, the NCCHC published separate standards for the accrediting of mental health programs in jails and prisons, Standards for Mental Health Services in Correctional Facilities. The most current NCCHC standards include the Jail (2018), Prison (2018), Mental Health (2018), and the Juvenile Standards (2018). The NCCHC also has developed standards for opioid treatment programs within correctional settings, which are linked to specific federal regulations.

Jails, prisons, juvenile detention, and other correctional facilities may be accredited by the NCCHC (an offshoot of the AMA as described previously), the ACA, The Joint Commission, or a combination of the above. Although national accreditation is typically voluntary, it is often a contractual requirement for universities, other health care systems, and private vendors who provide health care services to correctional systems. In addition, when facilities undergo investigation or litigation or are placed in receivership or federal oversight, they are often mandated to establish and maintain national accreditations.

Access to Mental Health Care and Treatment in Correctional Settings

Constitutional provision and statutory law require that an inmate in a correctional setting have access to mental health treatment, and this principle is emphasized in the APA Guidelines on Psychiatric Services in Jails and Prisons, which state, “Timely and effective access to mental health treatment is the hallmark of adequate mental health care.” In addition, it is striking to note that the very first standard of the NCCHC’s Standards for Mental Health Services in Jails and Prison is on access and requires that “inmates have access to care to meet their serious mental health needs,” defining access to care as meaning that “in a timely manner, a patient can be seen by a clinician, receive a professional clinical judgment, and receive care that is ordered” and adds that this principle is “the foundation upon which National Commission on Correctional Health Care standards are based.”

Furthermore, this section notes that access to care procedures should be flexible enough to accommodate inmates with mental illness and functional deficits and that such deficits can manifest as the following:

Telegram: @medical_k

www.konkur.in

- Inability to recognize emerging health or mental health need
- Inability to follow usual procedures in requesting health or mental health care
- Severe anxiety or suspicion preventing follow-up care
- Behavior that makes care especially challenging

Barriers to Inmates Receiving Services. To determine whether there is adequate and appropriate access to psychiatric treatment, it is critical that the treatment delivery system be analyzed to ensure that there are no unreasonable barriers to patients' receiving services. Some examples of unreasonable barriers listed in the APA Guidelines are listed in Table 58.3–3.

Table 58.3–3.
American Psychiatric Association Guidelines on Examples of Unreasonable Barriers to Patients' Receiving Psychiatric Services

Instituting or allowing disincentives that would deter a patient from seeking care for their legitimate mental health needs
Interfering with the prompt transmittal of a patient's oral or written request for care
Allowing unreasonable delays before patients are seen by mental health staff or outside consultants
Charging fees or costs that prevent or deter patients from seeking care
Punishing an inmate for seeking or refusing care

Staffing. The effectiveness of any correctional psychiatric system is largely dependent on staffing considerations. Staffing must be sufficient to ensure that every inmate with serious mental illness or in psychiatric crisis has timely access to evaluation by a competent mental health professional. More important than the number of staff is access to adequate care. Accordingly, none of the national correctional health care standards mandates staffing patterns other than that there be an adequate number and type to meet the needs of the population.

Screening. In jails and prisons, screening is critical, and, not surprisingly, both the APA Guidelines and the NCCHC Standards emphasize the importance of appropriate screening. The APA Guidelines

Telegram: @medical_k

www.konkur.in

describe in detail the sequence of screenings and assessments that lead up to treatment (Table 58.3–4).

For example, the APA Guidelines describe the progression in regard to an individual with a substance abuse disorder who might present while receiving mental health screening with any of a variety of medical, neurologic, or psychiatric problems. The receiving mental health screening instrument should include questions relating to the individual's use of alcohol and other drugs, the patterns of use, and observations related to whether the offender is under the influence of alcohol or drugs or experiencing withdrawal symptoms. The Guidelines note that the correctional psychiatrist should have an important role in the development of the screening instruments, in the training of staff in its use, and in educating correctional security, medical, and mental health staff about the signs and symptoms of intoxication and withdrawal.

A positive mental health screening for substance intoxication should trigger an immediate mental health screen for the presence of depressed mood and/or suicidal ideas. Similarly, the intake mental health screening should include questions on an inmate's history of alcohol and other drug use, as well as observations for the presence of signs of intoxication or withdrawal symptoms. The brief mental health assessment and the comprehensive mental health evaluation are particularly important in ensuring a proper diagnosis as the basis for the appropriate clinical management of an inmate with a substance use problem.

Table 58.3–4.
American Psychiatric Association Guidelines on Sequence of Screening and Assessments Leading up to Treatment

Screening
Receiving mental health screening
Intake mental health screening
Evaluation
Brief mental health assessment
Comprehensive mental health evaluation
Intervention

The NCCHC notes that "receiving screening" is the means by which "newly admitted inmates' emergent or urgent mental health needs are identified and met through an immediate referral to mental health staff."

Telegram: @medical_k

www.konkur.in

Both the APA and the NCCHC require a subsequent “intake” screening that must take place within 14 days. The step-by-step sequence ensures that an inmate who is identified through reception screening, intake screening, or by various processes at any time thereafter (including self-referral) as possibly in need of mental health treatment is provided with a suitable mental health evaluation.

Sick Call and Nonemergency Mental Health Care Requests and Services. Although the correctional psychiatrist works with inmates by appointment in an office situation if possible, in most correctional facilities, access to general health care is by means of “sick call.” The NCCHC Standards are quite specific and require that “all inmates have the opportunity daily to request mental health care” and that “verbal or written requests for mental health care are received daily by mental health staff and triaged within 24 hours.” There is a separate NCCHC standard for emergency services, and emergency mental health care is defined as “care for an acute mental illness that cannot be deferred until the next scheduled mental health clinic or routine appointment,” which must be available 24 hours a day, 7 days a week.

Referral. Emphasizing that within a correctional facility, the referral process is critical, and noting that this can be simple or complex, depending on the facility, the urgency of the situation, and the mental health coverage provided, the APA Guidelines state that the referral process, as set out in the facility’s operating standards, should be time constrained and specifically define the roles of the various participants, that the maximum time for response to each referral should be stated, and that timely referral and response should be designated as indicators of quality care.

Consultation. An important role of the correctional psychiatrist is to take the initiative in providing consultation to staff with regard to certain situations. Some of these are listed in the NCCHC Standards, such as consulting with regard to inmates who have a chronic illness (i.e., asthma, heart disease, diabetes, and hypertension) or communicable disease (e.g., HIV, hepatitis, syphilis, gonorrhea, or chlamydia); counseling patients coping with the psychological effects of their disease and consulting with regard to inmates who are physically or developmentally disabled and either assisting staff in managing such inmates or providing

Telegram: @medical_k

www.konkur.in

behavioral consultation so that the inmate can deal with the emotional and attitudinal consequences of their disability during incarceration. Consultations might also be called for with regard to inmates who are chemically dependent; pregnant or have recently given birth, for example, to minimize the postpartum phase and separation anxiety from the newborn; and of course, older adults or terminally ill inmates.

The Therapeutic Milieu for Mental Health Treatment. Table 58.3–5 lists the APA Guidelines conditions that would contribute to a therapeutic milieu for treatment.

Evidence-Based Treatment and Prescribing

Correctional psychiatrists must strive to provide evidence-based treatment as the standard of care in jails and prisons. Evidence-based treatments can be defined as treatments that, in appropriate studies, (1) have been rigorously tested, (2) have yielded consistent, replicable results, and (3) have proven safe, beneficial, and effective for most people diagnosed with the particular mental illness. While some researchers might argue over the standards by which an intervention or treatment approach is judged to be evidence-based, there is general agreement that the term and designation imply that a given practice has withstood rigorous scientific examination

Table 58.3–5.
American Psychiatric Association Guidelines on Conditions That Contribute to a Therapeutic Milieu for Treatment

A therapeutic milieu implies the following conditions:
- A sanitary and humane environment
- Written procedures and adequate staffing to permit adequate observation
- Adequate allocation of resources for the prevention of suicide and assault
- Medical and mental health staff available to provide adequate treatment and supervision
- Social interactions that foster recovery
- The ability to transfer an inmate to an appropriate mental health facility when the foregoing conditions cannot be met

Telegram: @medical_k

www.konkur.in

The public mental health system must take steps to ensure that practice keeps pace with research. Because correctional psychiatry is a critical part of public psychiatry, it is appropriate to quote from the Report of the Criminal Justice/Mental Health Consensus Project, which describes the development of the concept as it promotes the utilization of evidence-based practices in public psychiatry:

> *In recent years, enormous advances have been made in treatments available for persons with mental illness. New medications have emerged; new services, supports, and interventions have proven effective. Researchers have conducted studies and collected data—they have developed an "evidence-base"—which demonstrate the effectiveness and applicability of some of these treatments and approaches.*

Of note, The APA publishes Practice Guidelines that provide evidence-based recommendations for the assessment and treatment of a wide range of psychiatric disorders of considerable importance to correctional psychiatrists, including acute stress disorder and post-traumatic stress disorder (PTSD), bipolar disorder, borderline personality disorder, psychiatric disorders related to HIV/AIDS, major depressive disorder, obsessive-compulsive disorder (OCD), panic disorder, schizophrenia, substance use disorders, suicidal behaviors, and others.

It is generally recommended that psychiatrists should use psychotropic medications in a safe and clinically appropriate manner and after a review of the potential risks, benefits, side effects, and alternatives. As with any mental disorder, barring maintenance treatment, it is unwarranted to prescribe psychotropic medications in the absence of distinct target symptoms or when placement and mental health follow-up services are unclear. To avoid risk management problems, it is generally recommended that medication be used according to U.S. Food and Drug Administration (FDA)—approved indications and doses, and if this is not preferred, then it is suggested that the correctional psychiatrist obtain and document a second opinion.

Precautions against abuse are necessary, and so, for example, it is recommended that directly observed therapy (DOT), crush and float, or other strategies be implemented for medications with particular overdose or bartering risks. The risk of medication diversion is an additional consideration, including diversion of medications with CNS effects that are maximized by nasal insufflation, injection, and other means of administration.

Telegram: @medical_k

www.konkur.in

Involuntary Treatment in Correctional Psychiatry. Because involuntary treatment is complex and changes depending on the jurisdiction, the APA Guidelines say only "the actual institutional policies and the decisions of the correctional psychiatrist in regard to the right to refuse treatment should conform with the rules and procedures of the jurisdiction in which the facility is located."

On the contrary, the importance of this subject is highlighted by the fact that there are two separate NCCHC standards that apply. The first, Informed Consent and Refusal of Mental Health Care, states, "All examinations, treatments, and procedures are governed by informed consent practices applicable in the jurisdiction" and notes that "the intent of this standard is to support the ethical principle that patients have the right to accept or refuse mental health interventions."

The second NCCHC standard, Emergency Psychotropic Medication, states, "Mental health staff follow policies developed for the emergency use of forced psychotropic medications as governed by the laws applicable in the jurisdiction" (the definition of "forced medications" is "those given without the patient's consent").

It should be noted that the terminology used in the NCCHC Standards is dramatically different from that generally used in psychiatry. As a rule, psychiatric facilities use terms such as "treatment over objection" or "refusal of medication." The Standards focus on the word "forced" and its implications. Thus, the discussion of the latter standard states:

> *This standard's intent is to have a clinically approved protocol for emergency situations when an inmate is dangerous to self or others due to a medical or mental illness and when forced psychotropic medication may be used to prevent harm, based on a prescriber's order. The standard supports the principle that psychotropic medication may not be used simply to control behavior or as a disciplinary measure.*

Treatment Planning. The correctional psychiatrist has been trained as early as medical school to understand the importance of a detailed, in-depth, professional treatment plan. In any context or location, this requirement is a crucial reflection of the necessary standard of medical and psychiatric care. This is reflected in the APA Guidelines, which, with regard to discharge planning, notes that "it is recommended that discharge planning be a part of the initial treatment plan." Similarly, the NCCHC Standards require that "mental health services are provided according to individual treatment plans." The standards examine this subject in considerable detail, requiring that "patients receive care that is

Telegram: @medical_k

www.konkur.in

tailored to their individual needs . . . [including] consideration of cultural and language differences."

Peer-to-Peer Programs. Peer-to-peer programs have proven their worth in prison ministries, chaplain volunteers, and other spiritual ministries. Other peer activities may include volunteer work, providing care and training to service dogs for Veterans, and other individuals with disabilities, for example, the Patriot Paws programs. There are other self-help peer-to-peer organizations such as Alcoholics Anonymous (AA) and Narcotics Anonymous (NA). This concept is being extended into areas of reentry and continuing postincarceration support.

The APA Guidelines state, "As safety and security allow, self-help and peer support programs or activities contribute to the overall goals of the psychiatric services and where and when available should be promoted and encouraged."

However, within the correctional community, this is not an uncontroversial area. Concerns about the power of inmate workers were cited earlier. There are valid security concerns about prior inmates working within a correctional facility.

Suicide Prevention. The risk of suicide is dramatically higher among incarcerated jail and prison inmates than among the population at large. Suicide rates for men in jails are approximately 9 to 15 times higher than for the general population, and prison suicide rates are approximately 1.5 times higher than in the general population. An increased risk of suicide associated with mental illness also has been found. Researchers examined psychiatric disorders and completed suicide in the nation's largest state prison system, and their findings highlight the importance of maintaining suicide prevention programs in correctional settings with particular emphasis on screening and monitoring of patients with severe psychiatric disorders. It is further a legal requirement that every jail and prison must have a suicide prevention program that identifies and responds to each suicidal inmate and takes an active approach to their management.

An essential standard from the Jail, Prisons, Juvenile and Mental Health Standards of the National Commission outlines that an "adequate" suicide prevention program in a particular jail or prison should include the following components:

Telegram: @medical_k

www.konkur.in

- Training for all staff who interact directly with inmates to recognize warning signs and intervene appropriately with individuals at risk for suicide.
- A formal and detailed suicide risk assessment process.
- Identification of inmates at increased risk of suicide through screening at or near the time of admission to the facility and through referral at any time during an individual's incarceration.
- An effective and well-understood referral system that allows staff and inmates to bring a suicidal inmate to the prompt attention of a mental health clinician.
- Timely evaluation by a mental health clinician to determine the level of risk posed by a referred inmate.
- Timely implementation of monitoring interventions such as close observation (at least every 15 minutes), continuous monitoring, alternative housing, or referral to a higher level of care (e.g., infirmary or hospital). When indicated, a psychiatrist either on call or in person assists in the decision about interventions. Any mental health clinician may order an increase in monitoring level, but a decrease in level may be ordered only by a psychiatrist or doctoral-level mental health clinician after an in-person evaluation.
- Housing options that allow for adequate monitoring of suicidal inmates by staff. Suicidal inmates should not be placed in isolation settings without continuous monitoring. Continuous monitoring for active suicidality should occur regardless of housing location. Supervision aids such as video monitoring may be used as a supplement to, but not as a replacement for, active staff monitoring.
- Communication among mental health, correctional, medical, and other staff of the specific needs and risks presented by a suicidal inmate.
- Timely provision of mental health services, including medication, individual and group therapies, and crisis intervention, for chronically or acutely suicidal inmates.
- Accurate, behaviorally specific, and highlighted documentation in the medical record of behaviors or statements that indicate suicide risk.
- Quality improvement reviews with psychiatric staff participation in suicide attempts and completed suicides to help prevent future occurrences.
- Critical incident support, opportunities for peer-to-peer discussion, and availability of Employee Assistance Program support for completed

Telegram: @medical_k

www.konkur.in

suicides to assist staff and inmates in dealing with feelings of guilt, fear, grief, and anger.

HIGH-RISK PERIODS. It is obvious that an inmate might become suicidal at any point during incarceration. The high-risk periods that both the APA Guidelines and the NCCHC Standards emphasize are listed in Table 58.3–6.

Table 58.3–6.
Periods of High Risk for Suicide in a Jail or Prison

At the time of admission to a lockup, jail, or prison
After new legal problems (e.g., new charges, additional sentences, institutional proceedings, denial of parole)
After receiving bad news regarding one's self or one's family (e.g., a serious illness in the family or the loss of a loved one)
After suffering humiliation or rejection (e.g., sexual assault)
On being placed in administrative segregation or other specialized single-cell housing assignment
In the early stages of recovery from severe depression

Monitoring for and Preventing Self-Harm. Although there are many more suicide attempts and incidents of nonlethal self-harm than completed suicides, any threats of self-harm or self-injurious behavior must be taken seriously. Self-harm behaviors, regardless of motivation, can result in significant morbidity and mortality. For this reason, even behaviors that do not lead to injury should be taken seriously and not dismissed as merely "suicidal gestures."

Because self-harm is hard to control, it is a serious challenge for correctional officials and a complex clinical situation for the correctional psychiatrist, who must determine whether the self-harm is the result of a mental disorder. This requires a variety of means to assess the problem, including risk assessment methods and protocols and might require temporary housing in a mental health unit.

When self-mutilation is determined not to be the product of a mental disorder, the inmate may be denied admission to a mental health unit. This may confuse family members, attorneys, courts, patient advocates, and correctional authorities, who view such behavior as a sign of mental

Telegram: @medical_k

www.konkur.in

instability. It is, therefore, essential that the correctional psychiatrist follows clear protocols for self-harm to determine whether it is a psychiatric symptom, a manipulative gesture to escape a dangerous situation, or an effort to manipulate the system for personal gain. Careful and thorough documentation and communication with custody personnel are the key factors. Treatment, however, must be individually tailored and calls for a team approach.

Seclusion and Restrain in Correctional Psychiatry. Both the APA and the National Commission have addressed the complex issue of seclusion and restraint in correctional facilities. In 2006, the APA published the Resource Document on the Use of Restraint and Seclusion in Correctional Mental Health Care, which provides a detailed and nuanced discussion of this complex topic. It is strongly recommended that every practicing correctional psychiatrist carefully study and review this document. It "discusses the use of seclusion or restraint for purposes of mental health intervention in jails and prisons, in contrast to its use for correctional purposes (i.e., specifically custody reasons)."

With regard to the correctional setting specifically, this APA Resource Document details such matters as the location where the restraints or seclusion are being employed, the time frames that are required, and the devices that are permissible under various circumstances. The same principles are contained in the NCCHC Standard entitled Use of Restraint and/or Seclusion for Mental Health Reasons, which states, "Clinically ordered restraint or clinically ordered seclusion are available for patients exhibiting behavior dangerous to self or others as a result of mental illness." The standard further distinguishes between "custody" restraint or punitive segregation initiated for security concerns and "clinically ordered" restraint or seclusion initiated by medical or mental health staff as a therapeutic intervention when there are clinical concerns requiring intervention.

There remains a great amount of controversy regarding the empirically validated psychological effects of segregation and what effects, specifically, this has on individuals with or without serious mental illness. In sum, it appears that prolonged segregation exposes individuals to potential psychological, physiologic, and medical risks. Those with SMI have a special vulnerability to the adverse effects of social isolation. Psychiatrists should assist correctional systems with the development of

Telegram: @medical_k

www.konkur.in

evidence-based behavioral interventions that avoid the potential harm of social isolation.

The NCCHC Standard broadly defines segregated inmates as “those isolated from the general population and who receive services and activities apart from other inmates.” These housing units can be labeled as “administrative segregation, protective custody, disciplinary segregation, or a supermax tier.” It notes that “for the purposes of this standard, the living and confinement conditions define the segregated status, not the reason an inmate was placed in segregation.” The NCCHC Standard has an additional category—“extreme isolation”—which “refers to situations in which inmates are seen by staff or other inmates fewer than three times a day.”

The APA Guidelines state that when an inmate is segregated for any reason from the general population, the responsibility to address serious mental health needs remains in effect (Table 58.3–7). Indeed, because of the stressful nature of segregation housing, facilities should make special efforts to assess and address mental health treatment needs in these settings. Although correctional psychiatrists should not be involved in the decision to place an inmate in disciplinary segregation, once an inmate is there, the psychiatric staff should monitor their mental health status because an inmate who is placed in and is unable to cope with administrative segregation or other specialized single-cell housing assignment might also be at increased risk of suicide.

Telegram: @medical_k

www.konkur.in

Table 58.3–7.
The American Psychiatric Association Guidelines on Principles for Mental Health Services in Segregation Housing

The APA Guidelines recommend that in providing essential mental health service in segregation housing, the following principles should be observed:

- Inmates should be placed in segregation housing solely for correctional purposes and never because they exhibit the symptoms of mental illness, unless there is an immediate and serious danger for which there is no other reasonable alternative. (This principle does not refer to medical or psychiatric seclusion, which should follow state mental health law and professional practice.)
- When an inmate is placed in segregated housing for appropriate correctional reasons, the facility remains responsible for meeting all of the serious medical and psychiatric needs of that inmate. Thus, such inmates must receive any mental health services that are deemed essential, and require closer monitoring of psychiatric decompensation than in general population.
- Inmates who are in current, severe psychiatric crisis, including but not limited to acute psychosis and suicidal depression, should be removed from segregation until such time as they are psychologically able to tolerate that setting.
- Inmates who are known to have serious mental health needs or a history of one, when housed in segregation, must be assessed on a regular basis by qualified mental health practitioners to identify and respond to emerging crises at the earliest possible moment.
- Institutions should provide for regular rounds by a qualified mental health clinician in all segregation housing areas, and each inmate should be visited briefly to assess any emerging problem. The clinician should communicate with segregation security staff in order to identify any inmate who appears to be showing signs of mental deterioration or psychological problems.

Similarly, the NCCHC recommends, “inmates who are seriously mentally ill should not be confined under conditions of extreme isolation.” The Commission adds, “policies should also address how vulnerable populations like an adolescent, older adults, pregnant or mentally ill

Telegram: @medical_k

www.konkur.in

inmates are managed in segregation. Since segregation can exacerbate pre-existing conditions, staff should be extra cautious when placing vulnerable inmates in segregation." Similar position statements have been published by the APA (2017), and the SCP (2013).

Institutional Transfers. Classification committees continuously juggle custody and medical classifications of inmates with their workforce requirements and available space. Most institutions provide a list of the next day's transferees to the correctional psychiatric staff so that they can assemble the inmate's mental health records. Correctional psychiatric staff should ensure that the receiving unit has the requisite psychiatric resources to continue to meet the patient's needs. Each facility should have a policy that allows psychiatric staff to put a psychiatric hold on any interunit transfer of an inmate. Decisions regarding admission to and discharge from inpatient facilities are the sole provinces of clinicians.

Disciplinary Hearings. As a rule, correctional psychiatric staff should not participate in disciplinary hearings and should never be part of the punishment decisions. However, there are occasions when information from psychiatric staff might be helpful in protecting the inmate from inappropriate discipline. For example, a schizophrenic patient might refuse to comply with a correctional officer's directions because of negativism rather than defiance.

Discharge Planning. Studies of recidivism among persons in the justice system with mental illness indicate that effective discharge planning is essential to the continuity of care and a critical part of adequate psychiatric treatment in jails and prisons.

Despite court interventions developed for detainees with mental illness, there is still a lack of coordination and continuity of care for such persons on release. After incarceration, former inmates with mental illness have residential, financial, health, and mental health needs. Face-to-face linkage with community services has the greatest likelihood of success. Because most jails cannot control the court's release decisions, they usually do not know when an inmate is to be released, and so most jails do not provide case management or discharge planning services. To provide such services, discharge planning must start at admission. Providing uninterrupted medications after release is an important challenge. Without psychiatric medications, recidivism is almost inevitable.

Telegram: @medical_k

www.konkur.in

As the APA Guidelines state, “Timely and effective discharge planning are essential to the continuity of care and an integral part of adequate mental health treatment.”

This is true whether the patient is being released into the community or transferred to another correctional facility. Because discharges (e.g., from jails) or transfers (e.g., between prisons) can occur on short notice, it is recommended that discharge planning be a part of the initial treatment plan. Essential services that should be included in adequate discharge planning are psychiatric assessments, appointments to be arranged, notifications, staff responsibilities, linkages to community-based services, help with the obtaining of necessary financial benefits (e.g., Medicaid) and housing (due to the high incidence of homelessness in the jail and prison populations), placements, and appropriate linkages.

The NCCHC Standards suggest a number of components for a discharge-planning program:

- Formal linkages between the facility and community-based mental health organizations
- A list of community-based mental health providers that is used for referral
- An inmate education session that emphasizes the importance of follow-up aftercare
- Arrangement for follow-up mental health services before an inmate’s release
- Preparation of mental health summaries
- Assistance to inmates with their application to entitlement programs
- If appropriate, a supply of medications provided at the time of the inmate’s release

Reentry Programs. Whereas discharge planning is an aspect of services in jails and prisons, the last few decades have seen the proliferation of reentry programs, which can provide discharge planning and transition services to people with mental illnesses being released from city jails or state or federal prisons. These programs (usually government-funded—generally state or county) evaluate, select, and then actively link (and follow-up) the inmate with mental illness reentering the community to a wide variety of services, including intensive case management, mobile services, outpatient treatment, psychiatric

Telegram: @medical_k

www.konkur.in

rehabilitation, housing, vocational and educational services, access to entitlements, family supports, and substance abuse treatment.

This important area of reform of the correctional system gained added impetus from the Second Chance Act of 2007, federal legislation designed to ensure the safe and successful return of prisoners to the community by providing the following: Grants to states and local governments to promote the safe and successful reintegration into the community of individuals who have been incarcerated, including employment services, substance abuse treatment, housing, family programming, mentoring, victims services, and methods to improve release and revocation decisions using risk-assessment tools; grants to nonprofit organizations that can be used for mentoring adult offenders or offering transitional services for reintegration into the community; grants to improve the availability of drug treatment to offenders in prisons, jails, and juvenile facilities; and grants to states, local governments, and Indian tribes to develop and implement family-based treatment programs for incarcerated parents who have minor children. It also authorizes the U.S. Justice Department's National Institute of Justice and the Bureau of Justice Statistics to conduct reentry-related research and establishes a national resource center to collect and disseminate best practices and to provide training on and support for reentry efforts.

In a 2007 Task Force report by the American Psychiatric Association's Task Force on Outpatient Forensic Services, several barriers to successful re-entry following incarceration are identified; these included significant social isolation and stigma related to both mental illness and justice involvement; additionally, loss of social benefits such as SSI/SSDI, difficulties seeking housing, and the severe shortage of outpatient psychiatric services. Such gaps in access further contribute to the risk of recidivism and reincarceration among those released to the community without adequate supports.

Several types of programing have been proposed to aid in successful re-entry and reduce the risk of repeat justice involvement. Two examples include Forensic Assertive Community Treatment (FACT) and Critical Time Intervention (CTI). FACT aims to reduce rates of recidivism by engaging high-risk individuals with histories of justice involvement, increasing engagement in care through proactive outreach and wrap-around services. In contrast, CTI represents a 9-month, staged intervention that promotes individuals being linked to community services

Telegram: @medical_k

www.konkur.in

and support agencies. It has been shown to be effective at facilitating treatment engagement at the time of release from psychiatric hospitals and shelters, and the intervention has also been described as a promising model for facilitating re-entry from prisons for individuals who have a mental illness.

Each year correctional facilities release approximately 12 million inmates. Because society inevitably shoulders the cost of their treatment, the period of incarceration is an opportunity to create an infrastructure to identify and treat these patients. Effective correctional psychiatric systems will have a positive influence on the public's mental health. So, in recent years, it has become increasingly evident that correctional psychiatry must be considered an integral part of community psychiatry and that correctional health must be conceptualized as an important aspect of public health.

Additional Treatment Considerations and Special Populations

Women in Correctional Facilities. Although the number of women in jails and prisons is relatively small compared to the number of men, their percentage of the total correctional population is rising. Thus, at year-end 2006, women made up 7.2% of the population under state or federal jurisdiction, up from 6.7% in 2000. Until recently, most psychiatric treatment programs for women have been based on treatment models designed for men. It is now recognized that female inmates require very different screening, evaluation, and treatment, and with the reform of the correctional system, treatment programming provided to women in jails and prisons is changing dramatically.

As noted in the APA Psychiatric Services in Correctional Facilities, 3rd Edition: Female inmates frequently encounter different stressors before, during, and after incarceration than their male counterparts. More than 75% of women entering correctional settings report a history of emotional, physical, or sexual abuse as a child or adult. They have higher rates of domestic violence victimization than men. One aspect of this change is the recognition that female inmates have had high rates of victimization (sexual and physical), causing PTSD. The trauma of being raped before 16 years of age was the most frequently reported antecedent of PTSD among female prisoners. Such prevalence of trauma requires that a trauma-informed lens be applied to the provision of care in correctional

Telegram: @medical_k

www.konkur.in

settings, as well as to the utilization of potentially traumatizing interventions such as seclusion and restraint.

Demographic studies have shown that compared to men, a greater percentage of women entering a jail or prison have a serious and persistent mental illness. Although the rates of bipolar disorder and schizophrenia are similar for incarcerated men and women, a much larger percentage of women are diagnosed with major depression and severe anxiety disorders, especially PTSD. In addition, a higher percentage of women than men in jails and prisons enter these settings with a history of substance abuse.

Programming for women in correctional facilities must also consider that most women in correctional settings have dependent children and at least one child for whom they have been the primary caregiver. Their concerns about their children require special counseling on parenting and perhaps child custody. It is additionally important to attend to the health and mental health care of women who are pregnant or who have given birth recently. The correctional psychiatrist should be alert for and should minimize the risks associated with peripartum depression and psychosis, other adjustment disorders, and distress, and ensure that the facility establishes a policy that a comprehensive mental health evaluation be conducted or has any mental health problems during the pregnancy, delivery, or postpartum period.

Table 58.3–8.
American Psychiatric Association Position Statement on Treatment of Substance Use Disorders in the Criminal Justice System (2016)

1. Consider drug court and similar alternatives whenever they may be viable options to divert individuals from the criminal justice system.
2. All inmates should be screened by trained professionals and assessed for the presence of substance use disorders, withdrawal symptoms, and comorbid psychiatric illness, in addition to Hepatitic C, tuberculosis, and HIV.
3. Treatment for the above should be available within correctional facilities, or alternatively the ability to arrange timely transfer to an appropriate medical facility should be available. Health professionals should be able to screen for withdrawal.
4. Pharmacologic therapies, relapse prevention strategies, and psychotherapy for substance use disorders should be available for arrestees and inmates with substance use disorders.
5. Probation or parole should be conditional on receiving treatment for the substance use disorder whenever appropriate and clinically recommended. Furthermore, community treatment resources and access to care should be ensured upon release.

Data from American Psychiatric Association. *Position Statement on Treatment of Substance Use Disorders in the Criminal Justice System*. American Psychiatric Association; 2016.

Inmates With Substance Use Disorders in Correctional Facilities. The correctional psychiatrist must have knowledge and familiarity in the assessment and treatment of incarcerated individuals with substance use disorders because it is estimated that up to 70% to 90% of offenders have a substance use disorder at the time of their entry into the criminal justice system, and criminal behavior often occurs when an individual is under the influence of alcohol or other drugs. Furthermore, notably, some serious suicide attempts and completed suicides in jails may occur within the first 24 to 48 hours of admission and are often carried out by inmates who are either intoxicated or experiencing withdrawal symptoms. In 2016, the APA Assembly and the APA Board of Trustees approved a revised position statement prepared by the APA Council on Addiction Psychiatry

Telegram: @medical_k

www.konkur.in

on the treatment of substance use disorders in the criminal justice system, as shown in Table 58.3–8.

INMATES WITH CO-OCCURRING DISORDERS IN CORRECTIONAL FACILITIES. In 2006, the Bureau of Justice Statistics stated that about 74% of inmates in state prisons and 76% of jail inmates who had a mental health problem also met the criteria for substance use disorder. Nearly 63% of state prisoners who had a mental health problem had used drugs in the month before their arrest, compared to 49% of those without a mental health problem. For the correctional psychiatrist, the nondetection of one or more co-occurring disorders in jails and prisons risks the exacerbation of any behavioral problems and elevates the risks of suicide and poor outcomes in treatment.

For these reasons, the APA Guidelines recommend that the detection of one type of disorder (i.e., substance use or mental illness) immediately triggers an investigation into the other type of disorder. The importance of a coordinated system of screening, referral, assessment, and diagnosis for co-occurring mental health and substance use disorders is that one type of disorder can mimic the other, interfere with detection of the other, or overshadow the other type, and one type might affect the presentation of the other type of disorder. Table 58.3–9 lists the recommended APA Guidelines strategies for inmates with co-occurring disorders.

Telegram: @medical_k

www.konkur.in

Table 58.3–9.
American Psychiatric Association Guidelines on Recommended Strategies for Inmates with Co-Occurring Disorders

Services must integrate treatment that addresses the person's mental health and substance use disorders simultaneously.
Each type of disorder must be treated as a primary disorder, with a focus on understanding how they interact with each other.
Medication must be prescribed with caution. In individuals who are not on psychotropic medications, they should be fully allowed to detoxify from substances before starting medications unless psychotic or suicidal symptoms are present.
Psychosocial problems and skill deficiencies should be addressed with individualized programming.
Treatment should be integrated with self-help groups and support networks, which may be invaluable tools in assisting treatment participants in maintaining their commitment to daily alcohol and drug abstinence.
Interventions must be designed for the particular setting, each setting requiring differing intensity, length, and types of services.
The presence of co-occurring disorders requires special attention to discharge planning, which must address housing and job needs, family reconnection, and continued treatment.

The APA Guidelines emphasize that substance abuse services should be integrated with mental health services and that psychosocial problems and skill deficiencies should be addressed with individualized programming created through comprehensive assessment and consultation with the inmate's clinician, family (or significant others), and correctional medical and mental health clinicians.

In contrast to the APA position recommending the integration of services, the NCCHC in its standard on Substance Abuse Services relegates the roles of the medical and mental health staff to referral:

Increasingly, in larger correctional systems, inmates with [substance use] . . . disorders are receiving treatment for these problems from specialized treatment providers. Substance abuse counselors who treat [substance use] . . . problems should be properly qualified to do so by a recognized accrediting body. Medical and mental health care

Telegram: @medical_k

www.konkur.in

providers can facilitate the treatment process by referring inmates for treatment, providing counseling to motivate inmates to receive treatment, legitimizing self-help groups, tailoring controlled substances prescribing practices, and otherwise being a partner in the process of treatment.

There is an agreement, however, that inmates with co-occurring mental illness must not be barred from participation in substance abuse treatment programs and that self-help, 12-step, and peer support groups and networks play an important role in the rehabilitation of abusers of alcohol and other drugs in the correctional system.

DETOXIFICATION. When psychotropic medications are required during detoxification to manage medical or prevent impairment and sequelae, agitation and symptoms, or agitation, a physician must be responsible for managing the detoxification process.

Prescription of benzodiazepines might be useful to prevent or attenuate withdrawal symptoms and detoxify the inmate. However, their use should be short-term and on a tapering dose schedule to ensure that the prescribed medication does not serve as a substitute for the substance of abuse.

When circumstances warrant, an inmate should be detoxified or free from substance use for a reasonable period of time before psychotropic medications are prescribed unless psychotic or suicidal symptoms are present. The opiate- or other substance-dependent pregnant female presents special challenges to correctional systems, and a review of NCCHC standards and other accepted practice guidelines is recommended.

Inmates with Intellectual and Developmental Disabilities in Correctional Facilities. Offenders with co-occurring mental illness and intellectual or developmental disability encounter unique difficulties in the criminal justice system and have special treatment needs. From 4% to 10% of inmates have an intellectual developmental disorder (formerly referred to as mental retardation or borderline intellectual functioning), that is, significantly subaverage intellectual functioning and impairments in adaptive functioning, and “it is estimated that 40% to 70% of individuals with mental retardation in jails and prisons have diagnosable psychiatric disorders.”

This is a substantial number of inmates in the correctional population who have intellectual disabilities that present special problems for the

Telegram: @medical_k

www.konkur.in

correctional psychiatrist. According to the APA Psychiatric Services in Correctional Facilities, inmates with an intellectual or developmental disability and co-occurring mental disorders are unfortunately the most likely to be victimized by other inmates. Furthermore, custody and treatment staff need additional training and education on intellectual and developmental disabilities to lessen the likelihood that they misperceive behaviors as intentional rule infractions or attribute them solely to intellectual disability while an SMI goes untreated.

Geriatric Inmates in Correctional Facilities. The Federal Bureau of Justice Statistics notes that the U.S. prison population is aging and that "expressed in terms of percent change, the oldest age group, inmates age 55 or older, recorded the largest change—an increase of 85 percent since 1995." Effective access to mental health services for older inmates requires recognition of the special challenges facing inmates and mental health professionals, especially as the number of offenders older than 65 years in state and federal prisons increased at 94 times the rate of the overall sentenced population between 2007 and 2010. The aging of the correctional population will be a major problem in the 21st century.

As noted by the APA Guidelines, for the correctional psychiatrist, older inmates have medical needs that sometimes might present with psychiatric symptoms and might complicate psychiatric intervention in terms of medication, relevance of counseling, structure of time (programming) of the inmate, and housing. These problems are more likely to be chronic, permanent, and progressive, might be related to the possibility of dying in custody, and might be expensive (Table 58.3–10).

For the older inmate, the isolation can be expressed in a variety of ways and, when extreme, can exacerbate or create mental illness or psychiatric crisis. Special issues are related to (1) acceptance after release from incarceration, (2) provision of food, shelter, and clothing after release, (3) assault and potential greater sequelae of injury, and (4) isolation from older, "free" relatives and friends who might be unable to travel to visit.

Telegram: @medical_k

www.konkur.in

Table 58.3–10.
The APA Guidelines on Psychosocial Concerns of Older Inmates

Lack of connection to or interaction with other inmates in the general population, given the relatively small (though increasing) percentage of older inmates
Physical vulnerability to more serious consequences of assault
More difficulty and greater length of time to adjust to a new environment
Higher rate of completed suicide
Greater possibility of dying during incarceration
Higher incidence of loss of external supports, for example, spouse, parents, friends, and other external supports

Some of these issues might benefit from mental health intervention, including group or peer counseling. Psychiatric and clinical staff need training in the special needs and care required by older inmates, and they can help educate custody staff to recognize and deal with cognitively impaired inmates who might not respond appropriately to a direct order, mobility issues, and those who might demonstrate early confusion and cognitive impairments and associated sight and hearing impairments.

The Dying Inmate. Facilities should have written policies and training to address the in-custody dying inmate–patient. When feasible, the care of an inmate with terminal illnesses should involve the use of a hospice approach—a facility that emphasizes providing support and humane care to a dying patient rather than trying to cure the underlying disease. This might be inside the prison (less likely to be needed in jail) or a contract facility outside of the prison. Another consideration is the use of compassionate release (also called “medical parole”), which is available in a majority of states. Compassionate release can have a number of advantages, including cost savings for the prison health care system, which can be substantial.

The use of inmate volunteers (peer trainers) who are oriented on basic health issues, universal precautions, and mobility management can reduce the dying inmate–patient’s (or their family’s) perception that “the prison isn’t doing enough.” Group therapy, realistic planning, and suicide

Telegram: @medical_k

www.konkur.in

prevention are specific interventions that the psychiatrist should either provide directly or ensure provision by other mental health professionals.

The policy of “compassionate release” refers to the ability of institutions to grant early release or parole to individuals suffering from severe illness while incarcerated; these policies are based on the recognition that in cases of severe illness, appropriate treatment is difficult, if not impossible, to achieve in correctional settings. As the older adult population within the correctional system has continued to grow in recent years, the policy of compassionate release has become increasingly relevant. However, very few individuals are successfully granted release under this policy. Ensuring evidence-based palliative care and compassionate preservation of dignity have been cited as important considerations among medical professionals advocating for the value of compassionate release programming.

Rape and Victims of Sexual Assault. A full description of the psychiatric assessment and prevention of sexual abuse and exploitation within the correctional setting is beyond the scope of this chapter. The following provides a summary overview.

In 2003, the Prison Rape Elimination Act (PREA) became federal law; however, this phenomenon continues to be a challenge to manage with regard to prevention and aftercare. The Bureau of Justice Statistics report for the year 2007 indicated that an estimated 60,500 inmates (or 4.5% of all state and federal inmates) experienced one or more incidents of sexual victimization involving other inmates or staff. Additionally, among the 146 prison facilities in the 2007 National Inmate Survey (NIS), which was conducted in 146 state and federal prisons between April and August 2007 with a sample of 23,398 inmates, six had no reports of sexual victimization from the sampled inmates, and 10 had an overall victimization rate of at least 9.3%.

The national PREA standards were released in 2012. There is now a need for compliance with this federal mandate for facilities in the fields of adult, juvenile, and community corrections. Both correctional staff and health care staff might need education, training, and psychological support in managing either victims or perpetrators of sexual assault. Both the NCCHC and the American Correctional Association (ACA) play a vital role in supporting correctional institutions in the implementation of and compliance with the health care aspects of the PREA with education,

Telegram: @medical_k

www.konkur.in

curriculum developments, and technical assistance. Specialty training on complicated PREA issues is available for the psychiatrist and medical and mental health care practitioners. The curriculum includes information on detecting and assessing signs of sexual abuse and harassment, medical forensic examination and forensic evidence preservation, and effective and professional responses and reporting. In August 2013, the U.S. Department of Justice began auditing facilities to ensure compliance with the Act.

Inmates Serving Life Sentences. Psychiatrists may encounter inmates with one or more life sentences, life without parole, referred to as "lifers." These individuals pose a unique challenge to the correctional psychiatrist. Because these individuals will not be released from prison, many usual incentives such as parole, token incentives, and the like have less effect.

The APA Psychiatric Services in Correctional Facilities notes that "inmates draw on many resources to assist their adaptation to incarceration, such as family contact, peer support, work, education, and spiritual pursuits, including the practice of faith-based traditions." Some individuals may lack these psychosocial resources such as no regular family contact, no visitors, no one on their visitation lists, no one to help fund their commissary purchases, family estrangement, and the like.

Inmates on Death Row. The care of "Death row" individuals, inmates housed on death row, who are awaiting exhaustion of legal appeals, or whose legal appeals are exhausted, poses a myriad of complicated clinical, ethical, and legal questions. Some examples of issues include the death row psychiatric assessment, considering "justifiable" depression, suicide risk management, individuals on death row who require psychiatric hospitalization, psychiatric treatment thereby restoring one's competency to be executed, and how to balance ethical/role boundaries between clinical and forensic work. Because of the lengthy appeals process and high stakes involved, mental illness and intellectual disabilities are commonly raised in postconviction proceedings, typically on Eighth Amendment claims (arguing that the execution of the mentally ill and/or mentally retarded constitutes cruel and unusual punishment).

Inmates with mental illness on death row present unique and complex ethical issues. Because the participation of a correctional psychiatrist in an execution would violate the principle of *do no harm*, Annotation 4 of

Telegram: @medical_k

www.konkur.in

Section 1 of the APA's Annotations states that "a psychiatrist should not participate in a legally authorized execution." Much has been written about the interpretation of the word "participate," and it is clear that the medical community is unanimous that any action that would further the implementation of an execution is prohibited. Furthermore, there is no doubt that this applies to evaluations of competency to be executed. However, what about the treatment of an incompetent inmate to achieve competency? This is a controversial area, and whereas in general, the correctional psychiatrist is obliged to provide treatment to patients in need to relieve suffering regardless of the subsequent nonclinical consequences, it has been suggested that physicians who are opposed to the death penalty not practice on death row. Similarly, it was held in the case of *State v. Perry* that the patient retains the right to refuse treatment and the state cannot treat over objection so as to impose the death penalty.

The NCCHC Standard "Inmate Executions" states that "Mental health staff does not participate in inmate executions" and sets out the following compliance indicators:

An inmate's treating clinician does not provide a competency evaluation for execution.

Mental health services staff members do not assist, supervise, or contribute to the ability of another individual to directly cause the death of an inmate.

Mental health staff members provide ongoing mental health services to inmates in death row as clinically indicated according to individual treatment plans.

It is noted that the intention of this standard is that mental health staff not be involved in any action that would directly cause the death of an inmate because such involvement in inmate executions poses an ethical dilemma: "In order to be effective mental health care providers, correctional mental health care staff must maintain an appropriate professional relationship with their patients. This relationship is lost when mental health care staff assumes a role in inmate executions." The NCCHC Position Statement entitled Competency for Execution recommends that "the determination of whether an inmate is 'competent for execution' should be made by an independent expert" and not by correctional psychiatric staff.

Lesbian, Gay, Bisexual, and Transgender Persons and Gender Dysphoria. According to the APA Psychiatric Services in Correctional

Telegram: @medical_k

www.konkur.in

Facilities, trauma and stigma experienced by lesbian, gay, bisexual, or transgender (LGBT), individuals can increase their psychological distress and decrease their willingness to seek mental health services. When incarcerated, they risk additional discrimination and abuse. Compared with heterosexual inmates, studies have reported that they have ten times the rate of sexual victimization by other inmates and up to three times the rate of sexual victimization by staff. This risk needs consideration on arrival at any correctional facility. LGBT individuals differ in degree of comfort with their sexual orientation or gender identity and whether they are “out” or “closeted.” Their choice about disclosure can change when moving from the community to jail or prison and between institutions. A respectful and nonjudgmental approach by the correctional psychiatrist can help LGBT inmates explore their choices and cope with their concerns. Transgender inmates, for example, may feel distress when housed in settings that do not allow them to express their gender identity or when they elect to stay closeted because of safety concerns. A therapeutic relationship in which they feel known by someone safe can improve emotional well-being.

The evaluation and treatment of gender dysphoria, formerly known as gender identity disorder, is a particularly challenging area. The evaluation, treatment, and decision-making processes of whether to continue, discontinue, or initiate hormonal treatment for offender patients are complicated, and even more so due to PREA audits and enforcement in corrections. Custody leadership makes decisions regarding classification, housing, transportation issues, and whether they allow access to gender-preferred clothing, toiletries, and housing assignments. Beyond hormonal treatment, many correctional systems do not have uniform policies about permissible treatment for transgender inmates. However, more recently, the courts have been ruling in favor of cases by inmates calling for sex reassignment surgery in the correctional setting, with some courts agreeing that denying such a surgery is a violation of the Eighth Amendment. Consistent with the prevailing position of professional medical organizations, including the APA, courts, and society in general, are increasingly recognizing gender dysphoria as a medical condition appropriate for treatment. The California Department of Corrections and Rehabilitation is credited as the first state system in the country to have implemented policies granting these surgeries.

Hunger Strikes in Jails and Prisons. Hunger strikes (the refusal of nutrition as a means of passive resistance) are a daunting problem in jails and prisons. Although the history of hunger strikes goes back at least to the Roman Empire and in the Western world, there is generally a right to go on a hunger strike that is protected as a matter of "privacy" or a "liberty interest" or can be regarded as an expression of free speech, clearly, in a correctional facility other factors come into play. Correctional authorities are charged with the "care and custody" of the inmates. Therefore, the following principles should apply:

- The correctional facility must provide for the evaluation of the situation for treatment if necessary and perhaps for legally allowable intervention.
- The medical services must provide for the evaluation of the medical stability of the inmate.
- The correctional psychiatrist must be available to evaluate such an inmate's psychiatric condition and whether there is a need for treatment.
- The correctional psychiatrist must also evaluate the motivation for the hunger strike and the inmate's capacity to understand the consequences of their actions and the medical decisions being made.

The majority of U.S. courts that have considered the question hold that an order to force-feed does not violate a hunger-striking prisoner's constitutional rights because the institution in which the inmate is housed is responsible for his care while incarcerated, and there are other compelling governmental interests, such as the preservation of life, prevention of suicide, and enforcement of prison security, order, and discipline, that outweigh any constitutional rights asserted. It is interesting to note, however, that international authorities argue to the contrary. International courts have tended to allow hunger strikes to proceed even to death or disability. Thus, forced feeding of prisoners is prohibited by the Tokyo Declaration of 1975 by the World Medical Association and affirmed in 1992 by the Declaration of Malta.

In 1994, the ACHSA adopted a Position Statement that allows forced feeding when the legal procedure for medication over objection has been followed:

The management of a hunger-striking prisoner presents an ethical conflict between the obligation to preserve life and relieve suffering on the

Telegram: @medical_k

www.konkur.in

one hand and the obligation to respect patient autonomy on the other. Correctional health care providers should make every reasonable effort to honor patient self-determination. However, the deprivation of freedom that incarceration imposes will affect decision-making of the inmate patient. Therefore, special efforts in patient education and counseling are indicated.

Since forced feeding is a form of involuntary treatment, the responsible medical authority must seek the consent of the court or a legally appointed guardian, following the local requirements for involuntary treatment. The physician should make it clear to the court and to all others concerned; however, that ethical medical conduct in this setting demands medical intervention to preserve life from actions that are self-destructive.

ACHSA members should give careful consideration to the development of policies and procedures that provide a responsible and compassionate approach to the hunger-striking prisoner and which make it clear that efforts will be made to intervene with forced feeding in order to save a life.

The APA Psychiatric Services in Correctional Facilities recommends the following:

> *Hunger strikes are considered a medical emergency, and psychiatrists are often asked to evaluate inmates to determine if they have the mental capacity to make an informed decision regarding continuation of the hunger strike. Psychiatrists can perform evaluations to rule out underlying mental illness as a cause of the hunger strike (e.g., suicidal depression or delusions regarding prison food).*

There is currently no consensus to guide psychiatrists in the United States on the ethical standards of force-feeding to end hunger strikes in correctional facilities. Although the World Medical Association and the AMA, with limited exceptions, have taken stands against the practice, the Supreme Court of Connecticut, in *Commissioner of Correction v. Coleman* (303 Conn. 800 SC 18721 [2012]), found that the state's interest in the inmate's health and legitimate penologic interests in the safety of the facility outweighed the inmate's right to autonomy. Furthermore, the court ruled that "force-feeding did not violate constitutional rights to free speech and privacy."

THE FUTURE OF CORRECTIONAL PSYCHIATRY

In light of the significant numbers of individuals in our nation's jails and prisons, and due to the significant burden of mental illness and psychiatric

Telegram: @medical_k

www.konkur.in

needs in this vulnerable population, future directions for correctional psychiatry involve developing policies and protocols to ensure equitable treatment and access to care.

Diversion and Community-Based Interventions

There have been increasing efforts to pursue alternatives to incarceration of persons with severe mental illness and substance abuse disorders. One of the most promising alternatives is the diversion model, designed to prevent or minimize detention of the nonviolent mentally ill and to divert persons with severe mental illness to appropriate community-based mental health services in lieu of incarceration.

Interventions may occur at various points of interaction between individuals with mental illness and the justice system (Fig. 58.3–5). Pre- and postbooking diversion programs may hold promise for addressing overcrowding in jails and prisons and ensuring that individuals with mental illness are directed toward treatment.

Prebooking programs involve the utilization of first-response programming to respond to crises in the community. Examples might include specialized police response teams, mental health professionals hired by police departments, and local mental health crisis teams who often have relationships with local police departments. Other prebooking interventions might include collaboration between the above entities as well.

Postbooking interventions can be jail-based, involving recognition and assessment of detainees with mental health needs so that they can be transitioned to a community-based treatment program. In contrast, court-based diversion might involve assessments performed by courthouse clinicians who perform assessments and engage in discussion with the prosecution, defense, and a judge to advocate for release dependent on adherence to a community treatment protocol. Some individuals may be seen in specialized mental health courts, where involved individuals have specialized training in mental illness and will connect the individual to treatment, with follow-up to ensure adherence to the mandated treatment program.

Assisted outpatient therapy (AOT), also known as “outpatient commitment,” is also being studied and implemented to address the burden of serious mental illness in the community and in institutions. To date, 47 states have approved AOT programming (Connecticut, Maryland,

Telegram: @medical_k

www.konkur.in

and Massachusetts are the three states that do not currently have AOT). AOT represents a means through which court-ordered treatment can be coordinated for patients with severe mental illness who have experienced recurrent hospitalizations, poor adherence to recommended treatment, and/or significant adverse consequences (such as violence or justice involvement) because of their mental illness. While principles of patient autonomy and beneficence undeniably necessitate continued efforts to engage patients in voluntary treatment, there are individuals who, due to severe mental illness, are unlikely to voluntarily engage in treatment for whom court-mandated treatment programs might be effective in reducing risk for adverse outcomes. In a revised position statement by the APA regarding these programs, it was recognized that involuntary outpatient commitment and AOT could be effective at promoting recovery when implemented systematically and for a sustained period of time, involving linkage to medication management and psychosocial services with proactive treatment models similar to those of assertive community treatment or intensive case management programs. The APA additionally recommends clear and consistent planning regarding consequences of treatment nonadherence in addition to ensuring that separate review and approval are obtained prior to consideration of involuntary medication administration in the community.

Education

In 1996, the Accreditation Council on Graduate Medical Education (ACGME) recognized the subspecialty of forensic psychiatry, which includes substantial correctional components. The didactic curriculum for the forensic fellowship training requires that the "psychiatric curriculum includes the . . . evaluation and treatment of incarcerated individuals," and the "clinical experience must include experiences in the . . . treatment of persons involved in the criminal justice system." In addition, "Clinical placement must provide [forensic fellows] . . . with experience in the evaluation and management of acutely and chronically ill patients in correctional systems such as prisons, jails, community programs, and secure forensic facilities."

However, though most psychiatrists do not choose to dedicate their careers to forensic psychiatry, the prevalence of justice involvement among individuals with serious mental illness necessitates all providers to feel comfortable managing the unique needs of this population. Despite the number of individuals receiving mental health care in correctional settings and despite the fact that many of these individuals will eventually transition their care back to community providers, only one-third of psychiatry residency training programs included a mandatory correctional rotation for all trainees. Furthermore, even in programs offering elective rotations in correctional psychiatry, very few residents elected to participate. As the field of psychiatry works toward meeting the immense mental health needs of individuals in jails and prisons, increasing trainee exposure to and awareness of correctional psychiatry will be crucial in developing solutions to this public health issue.

Using Technology in Corrections: The Electronic Medical Record and Telepsychiatry

Many county, state, and federal correctional systems have moved toward the implementation of correctional EMR systems. This is particularly helpful in multisite systems or high-volume intake facilities with rapid turnover, or alternatively in large systems where there is common movement, transfers, and turnover of inmates both intra- and intersystem. Thorough medical documentation is useful protection against litigation to help clarify an individual's assessment and treatment plan and to ensure continuity of care.

Telegram: @medical_k

www.konkur.in

Telepsychiatry is another tool with significant promise in relation to meeting the need for mental health care in correctional settings, with the COVID-19 pandemic highlighting the potential benefits of telepsychiatry. Greater comfort by correctional psychiatrists and other mental health professionals with this technology increases the accessibility of expeditious services for patients, and due to less need for off-site transport for psychiatric evaluation, this technology reduces the cost and burden on staff to travel with an offender. More recent evidence has demonstrated the feasibility and efficacy of telepsychiatry in correctional settings. Furthermore, recent legislation in some states requires payment parity for virtual psychiatric encounters, further increasing the sustainability of virtual care in correctional settings. Despite its promise, challenges associated with the use of telehealth technology may include difficulties with rapport building, lack of trust between patient and provider, decreased efficiency of communication, and lack of provider awareness of facility events contributing to the individual's presentation and treatment.

Advocacy

A confluence of forces is accelerating the reform of the correctional system to the benefit of correctional psychiatrists and their patients. Intense advocacy efforts, especially by family members of persons with serious and persistent mental illness in the criminal justice system, through patient advocacy groups such as the National Alliance on Mental Illness and Mental Health America, are becoming increasingly effective in lobbying legislatures to increase mental health funding, staffing, and psychiatric services in jails and prisons.

Advocating around improving mental health laws in each state is an important way to reduce the incarceration of the mentally ill. Mentally ill individuals engage in violence in rare instances. However, when they do, it is frequently in the setting of acute untreated mental illness and substance use. Because the treatment does not always follow the patient outside of hospital walls, building treatment programs monitored and supported by courts in lieu of jail time can be an important way of protecting the autonomy and freedom of mentally ill individuals and reducing the time they are in a locked setting. Better laws that support mentally ill individuals receiving proper treatment also destigmatizes both psychiatric illness and its treatment. The Treatment Advocacy Center is promoting research in this area to help the public better understand

Telegram: @medical_k

www.konkur.in

mental illness, the pathways to incarceration for the mentally ill, and solutions, through treatment, to reduce the institutionalization of this vulnerable population.

Last, the APA is joining with other professional groups to develop programs and priorities for legislative action, including such groups as the Campaign for Mental Health Reform and the Mental Health Liaison Group. This has, in turn, drawn the attention of county and state governments not only in terms of the requirements of the humane aspects of care and treatment and concerns about litigation but also the financial and societal benefits of preventing mental illness-associated recidivism through jail and prison mental health programming, diversion programs, drug courts, and mental health courts, jail-based and other competency restoration programs, and well-developed reentry programs.

ACKNOWLEDGMENT

This chapter represents an update and revision of previous chapters in this series, most recently by Henry C. Weinstein, MD and Joseph V. Penn, MD from the last edition. We are indebted to Drs. Weinstein and Penn for their work and retain much of their prose in this current edition.

59 History of Psychiatry

EDWARD SHORTER, PH.D., F.R.S.C.

Motto: "In the natural sciences old views and interpretations of observations are overtaken by new discoveries and retain historical interest only; in the humanities this is never quite the case. Psychiatry has one foot in each of these disciplines and our heritage is not something we can simply leave to the historians." Julius Hoenig (1981). (Hoenig J. Psychiatric nosology. *Can J Psychiatry.* 1981;26(2):85.)

One of the earliest accounts of mental illness comes from the myths of the Greek gods. Hercules, under a delusive disorder, slays his children, believing them the offspring of another god.

One lad stretched forth his hands, crying, "Oh, dearest father, do not slay me; I am thy son." But Hercules, "with savage rolling eyes," as the chronicler tells us, "brought his club down upon the golden-haired head of the boy and broke his skull. The other children and the wife are sacrificed by the same murderous fury."

The modern reader recognizes the diagnosis of delirious mania, which, like most other psychiatric ailments, is as old as the hills and built into the pathology of the human condition.

Across the millennia, there have been many other accounts of deluded and melancholy patients. Psychiatric illness has always been recognized as medical in nature. Yet psychiatry as a discipline arises only late in the 18th century. It was under the influence of the enlightenment that the prospect of relieving mental illness through institutional care was first broached. There had always been

Telegram: @medical_k

www.konkur.in

confinement, in the context of the noisome “hospices” that lodged indiscriminately the insane, the poor, the older adults, the medically ill, and the criminal alike. But the concept of dedicated mental hospitals stemmed from the late 18th century, surfacing first in Italy, then in France. In this manner, psychiatry became a specialty, not because its practitioners had special diagnostic or therapeutic skills but because they had the administrative abilities required to run these large institutions. For decades, the emphasis in international surveys of psychiatric facilities would be on architecture and layout rather than on diagnosis and treatment.

Before the late 19th century, there was no such thing as private practice psychiatry. Psychiatry as a discipline was based in mental hospitals, or “asylums”—a term first used in 1766 instead of “lunatic hospital”—and psychiatrists were called “alienists” on the grounds that the distracted mind had become alien. Ambulatory patients were seen in private practice by neurologists or general practitioners.

EARLY BEGINNINGS

The main storyline is the transition from traditional hospices to mental hospitals dedicated to treatment and recovery. Joseph Daquin, a psychiatrist in the Savoyard city of Chambéry, extolled in a work on The Philosophy of Madness (*La Philosophie de la Folie*) in 1792, the bringing of patients “from their fetid holes … to the freedom of a great but enclosed yard. Trained staff will accompany them everywhere and keep them in view; in the yard, warders will let them do whatever they like, simply ensuring that they do not escape, and neither endanger their own lives nor those of others. We will simply let them wander about at will for two hours, or in the interval between one meal and the next.” This is not the first description of the therapeutic asylum but certainly the first that extolls the therapeutic advantages of freedom and exercise.

Italy

Telegram: @medical_k

www.konkur.in

Most accounts of the history of psychiatry do not begin with Italy, a land that is largely silent on the historical radar. Yet, it was in Florence in the 1780s that modern psychiatry actually began. The key concept is “therapeutic institution,” admitting patients in the hope of relieving their distress rather than protecting society from them. The first therapeutic asylum was launched in 1788 when Vincenzo Chiarugi (“KEY-ah-ROO-jee”) opened the doors of the old Bonifazio Hospital, previously a typical hospice, exclusively to psychiatric patients. Here, he organized gardens for the patients, provided music, gave a structure to their day, and ensured proper meals and humane treatment. From 1793 to 1794, Chiarugi wrote a three-volume psychiatry textbook based on these experiences, *On Insanity (Della Pazzia)*, specifying that for psychological tranquilization, the patients should be kept in calm, quiet environments: “The sweet songs of gentle, moving music in many cases will represent the first-line treatment.” As for stimulating treatments, the patients should undertake moderate exercise in the asylum and at home. In treating melancholy, Chiarugi deemed it “absolutely necessary that … [the physician] finds his way into the patient’s heart, gaining his confidence and trust.” Chiarugi called this “the psychological treatment” (la cura morale).

Italian psychiatry received a reformist bump-up in 1821 when Antonio Galloni became head of the venerable San Lazzaro Asylum in Reggio Emilia in the north of Italy. Founded in the 12th century as a leprosarium, in the 18th century Reggio Emilia went over to receiving psychiatric patients, and Galloni implemented many of the French reforms (see below), given that Italian psychiatry in these years stood much under the influence of France (later, of Germany). Reggio Emilia’s later superintendents included Carlo Livi, who in 1871, at the beginning of his tenure, introduced Italy’s first farm colony, and Augusto Tamburini (from 1877, after Livi’s premature death), who began outpatient care with local families. Livi and Tamburini were among the leading figures in 19th-century Italian psychiatry, and Reggio Emilia stood as an international model for the villa system—rather than housing inpatients in giant barracks—and for the use of laboratories in patient care. Tamburini’s watchwords

Telegram: @medical_k

www.konkur.in

were "*scienza e amore—studio e benevolenza*" (science and love, research and kindliness).

France

Modern psychiatry was anchored in France in two of the great Parisian hospices that Louis XIV founded in the 17th century: Bicêtre for men and the Salpêtrière for women. The seminal name in French psychiatry is Philippe Pinel, who in 1793 became chief physician of the Bicêtre hospice. Pinel is often seen (in ignorance of the contributions of Chiarugi) as the very founder of psychiatry itself. Yet the contribution of Pinel is difficult to overstate because his Medical-Philosophical Treatise on Mental Illness in 1801 (*Traité Médico-Philosophique sur l'Aliénation Mentale*) became the first international textbook and initiated the centuries-long task (not completed today) of perfecting the nosology of the field. In 1795, Pinel became the chief physician of the Salpêtrière, where he remained until his death in 1826. Pinel is also remembered as an early, influential advocate of humane care, as opposed to the chains-and-beatings approach that earlier characterized asylum life.

Pinel's student Étienne Esquirol ("ES-kir-ole"), who in 1825, became chief physician of the French national asylum in the Paris suburb of Charenton, is seen as the virtual founder of social psychiatry, assessing social patterns in illness, and further refining Pinel's nosology (see below). Esquirol inspired the Law of 1838 that obliged each district (department) in France to have a modern asylum; the law became worldwide a model of modern psychiatric care.

The United Kingdom

England. The first therapeutic asylum in England was St. Luke's Hospital in London, founded by William Battie in 1750. Battie conceived admission to the hospital itself as having a therapeutic character, and in his *Treatise on Madness* (1758), he wrote,

Telegram: @medical_k

www.konkur.in

> The regimen [in madness] is perhaps of more importance than in any distemper. It was the saying of a very eminent practitioner in such cases that management did much more than medicine; and repeated experience has convinced me that confinement alone is oftentimes sufficient, but always so necessary, that without it every method hitherto devised for the cure of madness would be ineffectual.

Yet, until the opening of the Maudsley Hospital in 1923, the anchor of English psychiatry was Bethlem Hospital ("Bedlam"), founded in 1247 as a base for the Crusaders, then gradually given over to the care of the insane. (In 1930, the hospital removed from the district of Southwark to suburban Kent, at which time the old building—one of several over the centuries—became the Imperial War Museum.) The hospital is indissolubly linked with the Monro dynasty of psychiatrists, of whom Edward Thomas Monro was in office from 1816 to 1855. Among the hospital's medical officers, or "apothecaries," was John Haslam, author of Observations on Madness and Melancholy (1809), the detailed cases of which are among the earliest patient reports in psychiatry.

In the first half of the 19th century, England led in the international movement to asylum reform, emphasizing "moral treatment" (psychotherapy), which began late in the 18th century at the Quaker Retreat in York, and the "non-restraint" system of patient care (abolishing chains and the like) that John Conolly initiated after he became superintendent of the Middlesex Asylum at Hanwell (a London suburb) in 1839. "The old system," said Conolly in 1856, in his Treatment of the Insane without Mechanical Restraints, "placed all violent or troublesome patients in the position of dangerous animals. The new system regards them as afflicted persons, whose brain and nerves are diseased, and who are to be restored to health, and comfort, and reason."

Scotland. Psychiatry in Scotland was dominated by the Edinburgh Royal Asylum (today the Royal Edinburgh Hospital), founded in 1813 at the Morningside estate, out of dismay at how badly Scottish poet Robert Fergusson was said to have been treated at the London asylum of "Bedlam." (He died there at 24.) The Royal Edinburgh was led over the years by a series of major figures in the history of British

Telegram: @medical_k

www.konkur.in

psychiatry, such as Thomas Clouston, *whose Clinical Lectures on Mental Diseases* (1883) remained for years the standard textbook.

Ireland. How direly Ireland required modern psychiatry emerges from testimony before the House of Commons in 1817:

There is nothing so shocking as madness in the cabin of the Irish peasant, where the man is out laboring in the fields for his bread, and the care of the woman of the house is scarcely sufficient for attendance on the children. When a strong man or woman gets the complaints [severe psychiatric illness], the only way they have to manage is by making a hole in the floor of the cabin, not high enough for the person to stand up, with a crib over it to prevent his getting up. The hole is about five feet deep, and they give this wretched being his food there, and there he generally dies.

Until the foundation of the Irish Free State in 1922, Ireland was a colony of Great Britain, and Irish psychiatry rose simultaneously with English psychiatry. The Richmond Lunatic Asylum in Dublin (now St. Brendan's Hospital), the flagship of Irish psychiatry, was founded in 1816, and in 1857, Joseph Lalor became its first resident medical director. Given the absence of psychiatry in the medical curriculum until 1875, the only means of becoming a psychiatrist in Ireland, and in much of Scotland and England, was to serve as an assistant physician in an asylum. Irish clinicians of the day, such as Conolly Norman, a later superintendent of Richmond, favored the strong German emphasis on clinical psychiatry and found unhelpful the anatomical speculations of the era about causation (did the ovaries cause mental disease or not?).

German-Speaking Europe

"If French is the language of diplomacy, then German may be said to be the language of psychiatry," as Edward William Anderson, professor of psychiatry in Manchester, observed in 1962 after German had become a dead language internationally. In the years between 1850 and 1933, German was indeed the language of psychiatry, as it was the language of culture and scientific life in an

Telegram: @medical_k

www.konkur.in

enormous swath between Budapest (Hungarian psychiatrists all published in German) and Strasbourg, or between Hamburg and Vienna. Unlike England and France, where a single great city dominated the psychiatric life of the country, in German-speaking Europe, there was a profusion of small states and over 30 university psychiatric departments or psychiatric hospitals existed, most of which had scientific aspirations; by 1900, Heidelberg, Berlin, Munich, and Vienna had become world centers of psychiatric learning.

Austria-Hungary. Psychiatry in Vienna was symbolized by the famous Tower of Fools (Narrenturm), a roundish structure with 139 individual cells (that still exists today), built by Emperor Joseph II in 1784 as part of the Vienna General Hospital. Although it was soon overtaken by advances in care, it remained an emblem of the distinctiveness of Viennese psychiatry, which later gave birth to such figures as Sigmund Freud (psychoanalysis) and Manfred Sakel (insulin coma therapy—see below for both).

Germany (After 1871, United as the German Empire). In the early years, German psychiatry tended to be overshadowed by the French. Yet, there were spots of light. An important early figure was Wilhelm Griesinger, who, as an assistant physician to Ernst Albert Zeller in the Winnenthal asylum in the early 1840s, began to propagate the view that “mental disease is brain disease,” a main tenet of later German biologic psychiatry. In 1845, Griesinger expressed his views in a textbook, *Mental Pathology and Therapeutics* (*Die Pathologie und Therapie der psychischen Erkrankungen*), a second edition of which in 1861, became the leading international textbook of biologic approaches to the field. In 1865, Griesinger moved from Zurich to Berlin as a professor of psychiatry at the Charité Hospital; here, he founded in 1867 the *Archives of Psychiatry and Nervous Diseases (Archiv für Psychiatrie und Nervenkrankheiten)* that was the equivalent of *the Archives of General Psychiatry* (renamed *JAMA Psychiatry* in 2013) today.

Several reformed psychiatric hospitals flourished in Germany early in the century, including Siegburg north of Bonn, founded in 1825 by

Telegram: @medical_k

www.konkur.in

Maximilian Jacobi, who introduced to Germany the “no restraint” system—not shackling patients—and forms of psychotherapy. These reformed asylums also constituted centers of research as well as humane care, and in the days before the shift of scholarship to university psychiatric hospitals, an asylum such as Illenau in Achern (Baden), which opened its doors in 1842, under its inaugural director Christian FW Roller, was probably the intellectual center of German psychiatry; Roller tutored many clinicians who later became leaders of the field, including Richard von Krafft-Ebing (see below). In 1854, Jacques-Joseph Moreau (“de Tours”), after a visit to a number of German asylums, noted, “the great scientific movement” in German psychiatry. This was the beginning of a vast scientific take-off.

Scandinavia

In the history of psychiatry, the contributions of the Scandinavian lands have been largely neglected, partly for linguistic reasons, partly for cultural blinkeredness.

Denmark. New-style, reformed asylums arose early in the Nordic lands. Denmark had receptacles for the insane dating back centuries. The city of Copenhagen had traditionally confined the “lunatics” at a so-called plague house. Yet following the British bombardment in 1807, living conditions for these unfortunates became intolerable, and the city decided to place patients at a castle at Roskilde, not far distant from the town. The asylum, which began accepting patients in 1816, became known as St. Hans Hospital. But there were other Danish centers too. In the course of the century, neurosyphilis became a common reason for asylum admission. In 1857, Friedrich Esmarch and Peter Willers Jessen, at an asylum in the province of Schleswig (then belonging to Denmark), proposed in the *General Journal of Psychiatry* (*Allgemeine Zeitschrift für Psychiatrie*) that the mysterious fatal disease then called “progressive paralysis” seemed to be a late consequence of primary syphilis. A landmark in Danish psychiatry was the work of Copenhagen’s Carl Georg Lange, professor of pathology at the

Telegram: @medical_k

www.konkur.in

University and considered Denmark's "first neurologist," on "periodic depressive conditions," considered by Lange to be a separate illness for which he recommended lithium therapy.

Norway. As elsewhere in Scandinavia, psychiatry in Norway rested heavily on the German tradition of biologic and genetic investigation. The first state psychiatric hospital in Norway, Gaustad Mental Hospital, in a town of that name near Christiana, was founded by Herman Major, the "first psychiatrist of Norway," in 1855. Important research came out of Gaustad, including superintendent Hans Evensen's landmark studies of schizophrenia (showing different outcomes). In 1934, Ivor Asbjörn Fölling, a biochemist at the Rikshospitalet in Oslo, the Norwegian national research hospital, discovered the metabolic cause of a disease called phenylketonuria (PKU), one of the so-called "inborn errors of metabolism" and a cause of mental retardation: It was a genetic inability to metabolize the amino acid L-phenylalanine, causing toxic amounts of phenylalanine to accumulate in the brain.

Sweden. Georg Engström founded the first reformed asylum at Vadstena in 1829; thus, as scholar Lennart Wetterberg put it, "drawing a line between barbarism and humanity in Swedish psychiatry." National mental health legislation in 1858 stipulated that an asylum must be led by a physician. The teaching of psychiatry in Swedish universities, among the earliest such teaching anywhere, began in Uppsala in 1741, with Carl von Linné, the great classifier, lecturing on medicine, including psychiatry. At the University of Stockholm, called the Karolinska Institute, Eric Godelius gave the inaugural lectures on medicine, which embraced psychiatry as well, beginning in 1811. At Karolinska, later a world-famous research institute as well as a university, Wilhelm Öhrström, the first professor of psychiatry and simultaneously head of the newly built Konradsberg psychiatric hospital, began lecturing in 1861.

Spain

Telegram: @medical_k

www.konkur.in

Although an asylum was established at Valencia in 1409, the great clinical school of Spanish psychiatry that flourished in the Middle Ages had little continuity into the modern era. In the 19th century, Spanish psychiatry remained much under the influence of the French, and it was Madrid's Pedro Mata y Fontanet who established forensic psychiatry in Spain as the inaugural holder of the chair from 1843 when he helped introduce Esquirol's ideas. The overwhelming figure in modern Spanish neuroscience is Santiago Ramón y Cajal ("Ca-HAL"), who taught anatomy and pathology at the universities of Barcelona and Madrid. From 1888, Ramón established the neuron theory of brain histology and is generally acknowledged as the father of modern neuroscience (he received a Nobel Prize in 1906). His advice for a young investigator (1897, in Spanish) remains compelling reading for young scientists even today. Although he did not practice clinical psychiatry, many later prominent psychiatrists trained in the "Cajalian" phase of Spanish medicine (but note that he is generally referred to as Ramón, not Cajal, which was his mother's name). The main chairs of psychiatry were founded in the last years of the Second Republic (1931–1936), and the most important 20th-century clinical figure in Spanish psychiatry, Juan J. López Ibor, who originated the concept of "vital anxiety" (*timopatia ansiosa*), held the chair of legal medicine, toxicology, and psychiatry in Madrid from 1932.

United States

In 1751, the Society of Friends (the Quakers), assisted by Benjamin Franklin, founded in Philadelphia the Pennsylvania Hospital; it was the first institution in the United States to have a major psychiatric division, for "persons distempered in mind," opened by Benjamin Rush in 1793. Rush was one of the signers in 1776 of the Declaration of Independence and practiced as much general internal medicine as he did psychiatry in his years of service from 1783 to 1813. In 1812, Rush wrote the first American psychiatry textbook, *Medical Inquiries and Observations*, *upon Diseases of the Mind*—

Telegram: @medical_k

www.konkur.in

and thus earned the sobriquet “father of psychological medicine in America.”

The first state hospital in the United States opened its doors in 1773 in Williamsburg, Virginia. Called “The Public Hospital for Persons of Insane and Disordered Minds,” it later became the Eastern State Hospital. Meanwhile, a series of private and charitable psychiatric hospitals sprang up on the model of the Pennsylvania Hospital. In 1817, the Quakers, alarmed at overcrowding in the Pennsylvania Hospital, founded a Retreat in nearby Frankford, Pennsylvania. In 1818, the psychiatric division of the Massachusetts General Hospital (incorporated in 1811) was founded at Charlestown in Boston and named (after a private donor) the McLean Hospital. The Retreat in Hartford, Connecticut, opened in 1824 and still exists today under the name Institute for Living (see below).

In 1771, a charter was granted to The Society of the New York Hospital, and in 1791, New York Hospital began accepting patients, including psychiatric; in 1808, it constructed a separate “lunatic asylum” for this purpose. At this point, the reforms of Pinel and Tuke had begun to arouse interest in the New World, and shortly proposals for “moral treatment” were circulating in New York as well. The trustees of New York Hospital, therefore, purchased a lot fronting the Bloomingdale Road in Harlem, and in 1821 the new structure named the Bloomingdale Asylum was opened, receiving private patients as well as those subsidized by funds from the Society of the New York Hospital. Years later, the Society decided that country air might be more salubrious, and in 1894 transferred the Bloomingdale patients to a new site in White Plains, Westchester, where it became the Westchester Division of The New York Hospital-Cornell Medical Center (see below for further developments).

The first large state hospital run on enlightened principles in the United States opened at Worcester, Massachusetts, in 1833, under the leadership of Samuel B. Woodward, an enlightened and forward-looking psychiatrist and close friend of Eli Todd at the Hartford Retreat. Following a lobbying campaign by Dorothea Dix, the hospital was enlarged in 1835, and on several subsequent

Telegram: @medical_k

www.konkur.in

occasions, this victory marked the beginning of Dix's career as an advocate on behalf of poor people with mental illness. Among the most influential of the early American state hospitals was the Utica Hospital, opened in 1843, part of the vast New York State system of hospitals, which served as a seedbed for successful hospital administrators in many other institutions.

The shift in U.S. psychiatry from large buildings with long corridors to small villas clustered in village-like colonies began in 1894 with the foundation of the Colony for Epileptics in Sonyea, New York ("Craig Colony" after Oscar Craig, president of the New York State Board of Charities); the first patient was admitted in 1896. With colony care, these mental hospitals adopted a more human face.

THE FIRST BIOLOGIC PSYCHIATRY

The intellectual content of this budding young discipline was overwhelmingly biologic. At the beginning, psychiatry had a profound physical orientation. The brain was seen as the seat of diseases of the mind, and treatments addressed the brain and the body as a whole. In 1672, Oxford physician Thomas Willis (who described the "circle of Willis") said of the brain's role in his famous *Two Discourses Concerning the Soul of Brutes*

> When it happens that these corporeal functions are defective or hindered, forthwith the eye of the intellect, as if covered with a veil, is wont to be very much dulled or wholly darkened . . . Because [of] their powers being hindered … the imbecility and dullness of the mind, the slowness of the ingenuity, stupidity and madness at length do often arise. The fault is either in the brain itself, or the animal spirits, or both together.

For many decades, investigations of the brain to ascertain the correctness of Willis's views were hindered by the lack of suitable stains for nervous tissue. Studies of inheritance became the main technique of biologic psychiatry. But in the 1870s, a new school of neuropathology, seconded with the aid of the microscope, began to arise, and the findings of such investigators as Theodor Meynert in Vienna and Franz Nissl in Heidelberg (see below) gave new impetus to biologic thinking.

Telegram: @medical_k

www.konkur.in

Nerves

Intrinsic to biologic views was the assumption that disorders were caused by the nerves. Beneath the level of frank “insanity” or “madness,” depression, anxiety, obsessive-compulsive disorder, and other nonpsychotic complaints were thought nervous in nature. The view was that the nervous system was somehow physically affected and that the source of mental and behavioral symptoms lay in these ailing nerves. In 1780, Samuel Tissot of Geneva, whose practice included many patients with psychiatric disorders, said, “Among the most appropriate remedies for diminishing the irritation of the nerves, and to destroy numerous causes of their disorders, one must place the baths, cold or warm.”

By the mid-19th century, the concept of “nerves” had seized psychiatry in the way that “psychoneurosis” and “mood disorders” would later rule. English law distinguished clearly between insanity and nerves. As the asylum inspectors reported in 1844, “Homes which are licensed for the reception of Insane Persons ought to be kept exclusively for that purpose and the reception of nervous, imbecile, and dejected [depressed] persons, amongst those who are insane and often dangerous, is for obvious reasons open to serious objection.”

Psychiatrists were once called “nerve doctors,” a term that persisted in German-speaking Europe until relatively recently (Nervenarzt); a “nervous breakdown” crossed the threshold into psychosis, rendering patients incapacitated in a way that is associated with melancholic illness, acute psychosis, and delirious mania. In 1851, Henry Monro, an attending at St. Luke’s Hospital in London, said in his Remarks on Insanity, “The symptoms of insanity are simply the consequence of loss of nervous power.” He called insanity “simply a disease of deficient nervous vigour.” These words hallmarked a century of biologic psychiatry.

Predisposition, Degeneration

Psychiatrists have always believed that many mental illnesses can be passed on from generation to generation, that they are

Telegram: @medical_k

www.konkur.in

"inheritable," or the result of "predisposition." The psychoanalysts did not believe this and attributed reproducibility within families to "nurture" rather than "nature." Yet, in the great sweep of things, psychiatry as a whole has believed in nature. As London's John Haslam said in 1817, "The minute investigation of many hundred cases has fully satisfied my own mind that the offspring of a person who has labored under insanity, is peculiarly liable to become similarly affected." By the late 19th century, it had become an accepted fact that the main cause of psychiatric disease was "heredity." As Paris psychiatrist Ernest Billod toured Italian asylums in the early 1880s, he was struck at the mantra-like repetition of the phrase, "The predominant cause of mental illness is heredity."

Early Pharmacotherapy

In psychiatry's early period of biologic thinking, before the rise of psychotherapy, treatments of mental disease borrowed heavily from the "humoral" remedies employed elsewhere in medicine, mainly the therapies of "depletion": Correcting humoral imbalances in the body by venesection (on which Philadelphia's William Rush was very keen), leeching, and the administration of purgatives and laxatives. At the same time that depletion began to totter in the rest of medicine—toward the mid-19th century—it came under attack in psychiatry as well and was replaced by the whole world of physical and dietetic therapies. All such treatments rely mainly upon the placebo effect, but at least they are not, unlike depletion, actively harmful to the patient. As Woodward wrote in 1850,

> The abandonment of depletion, external irritants [mustard plasters], drastic purges and starvation, and the substitution of baths, narcotics, tonics and generous diet, is not less to be appreciated in the improved condition of the insane, than the change from manacles, chains, by-locks and confining chairs, to the present system of kindness, confidence, social intercourse, labor, religious teaching, and freedom from restraint. In this age of improvement, no class of mankind have felt its influence more favorably than the insane. (Woodward SB. Observations on the medical treatment of insanity. *Am J Psychiatry*. 1850;7(1):1–34.)

Telegram: @medical_k

www.konkur.in

There was in the mid-19th century a brief but lucid anticipation of the era of psychopharmacology that would follow a hundred years later: In 1845, Paris psychiatrist Jacques-Joseph Moreau (nicknamed “Moreau de Tours,” after the medical school he attended) published the results of his therapeutic experiments with hashish. The essence of psychopharmacology is establishing differential effectiveness, and in this foundational work, Moreau established that hashish was ineffective in the treatment of dementia and stupor (*stupidité*), but that it did seem to have antimelancholic effects, lifting the mood and abolishing psychotic ideation in two melancholic patients.

As for subsequent pharmacotherapies, the opinion is widely held that psychiatry possessed no pharmacologic treatments before the psychopharmacologic revolution of the 1950s (see below). This is false. Psychiatry has always disposed of a palette of agents, admittedly of varying effectiveness (yet that is true today, as well). Until the Second World War, the Germans led the pack. In the area of medicinal innovation, in the years 1800 to 1930, Germany had 44% of the world’s total innovations, followed by France at 16% and the United States at 14. The German chemical industry began its take-off around 1860, dyes in the forefront, and from the dyes emerged the first generation of psychopharmaceuticals. The very first treatments, however, were as old as the hills.

Ethanol. People are accustomed to thinking of beverage alcohol as a source of substance abuse rather than a useful therapeutic agent. Yet before the Second World War, although the dangers of alcoholism were readily acknowledged, alcohol constituted an important treatment. In 1923, Alexander Westphal, director of the university psychiatric hospital in Bonn, said, “In milder cases of melancholia, alcohol as a sedative and hypnotic can yield good service.” The opinion was typical of the psychiatry of the day and not necessarily incorrect.

Opium. The milky juice of the unripe poppy plant *Papaver somniferum* in the treatment of melancholia goes back to the

Telegram: @medical_k

www.konkur.in

Ancients and was revived in the 17th century by London physician Thomas Sydenham, who standardized a combination of opium and alcohol (sherry) in “laudanum,” or opium tincture. Practitioners of mental medicine began prescribing opium in the 18th century, and in 1788, William Falconer was found, in his discourse upon “the influence of the passions,” waxing enthusiastic: “Opium too, which has been introduced into practice of late years in the nervous fever, and frequently administered, and in pretty large doses, is well known to exert great cordial effects on the mind and spirits.” Tincture of opium does not seem to have been highly addictive because so much of the alkaloid is inactivated by stomach acids. But with the invention of the syringe in the 1850s, it became possible to inject opium, and the resulting epidemic of addiction caused many psychiatrists to back away from the poppy, which seems actually to be quite effective as an antimelancholic. Yet as late as the 1960s, Hoffmann-La Roche Laboratories marketed injectable opium (Pantopon) for indications including psychiatric.

Cannabis and Hashish. The derivatives of *Cannabis sativa* L have a long history of use—today quite forgotten—in psychiatric therapeutics. After Moreau’s work in 1845, hashish became widely prescribed. Auguste Voisin, the professor of psychiatry at the Salpêtrière in Paris, described hashish in 1883 as part of the panoply of agents, including potassium bromide and hydrotherapy which he deployed in the treatment of psychotic depression. Cannabis has a similar history of age-old use and was marketed as a drug in England in the 1930s under the brand name Indonad (in Germany as Indonal-Bürger). The cannabinoids became definitively stigmatized in the “war on drugs” of the 1970s and disappeared from psychological medicine.

Lithium. Lithium had drifted on and off the therapeutic palette for decades, if not centuries. Certain mineral springs in Texas containing lithium, for example, had a historic reputation as “crazy water.” In 1886, Copenhagen psychiatrist Carl Georg Lange proposed lithium in the treatment of melancholic depression. But the remedy did not

Telegram: @medical_k

www.konkur.in

catch on, as the concept behind it, a uric acid diathesis of mental illness, was soon abandoned. (On the later history of lithium, see below.)

Sedatives and Hypnotics

Medicine's encounter with sedatives goes back to 1857 when the salts of bromine ("bromides") were introduced. Among chemically synthesized sedatives, chloral hydrate followed in 1869 (and is still in use today). Paraldehyde was introduced in 1882, and a number of other synthetic sedatives were launched—all now long forgotten. The barbiturates, however, were one of the major drug classes of the 20th century. A mixture of uric acid and malonic acid, the first barbiturate, barbital sodium (Veronal), was marketed in 1903, phenobarbital (Luminal) in 1911, and then dozens of shorter half-life preparations, including amobarbital (Sodium Amytal) in 1924 and butabarbital (Butisol) patented in 1932. These agents became household names and were widely prescribed.

Despite this proliferation of agents for mild depression and anxiety, psychiatry lacked treatments for such major illnesses as schizophrenia, melancholic depression (with the exception of opium), and catatonia. In 1892, Daniel Cathell, a Baltimore physician whose practice was heavy with nervous patients, advised his colleagues,

> Should you ever have recourse to remedies intended to act chiefly through the mind, look your patient earnestly in the face … they will do double good.…You will not only find that almost anything will relieve some of these cases, but will be further surprised to learn that it has evoked great mental and spiritual enthusiasm, and that they are chanting its praise and vowing that they were cured of one or another awful thing by it.…Some, indeed, who seem to be magically benefited by doses of—nothing—will actually credit them with saving their lives. (Cathell DW. *Book on the Physician Himself: And the Things That Concern His Reputation and Success*, The Twentieth Century Edition. F.A. Davis; 1903:190.)

The jury is still out on whether this happens today. (This thread is continued below under "The Psychopharmacologic Revolution.")

PSYCHOTHERAPY, SOCIAL PSYCHIATRY

Telegram: @medical_k

www.konkur.in

Early Psychotherapy

Although physicians have always practiced an informal kind of psychotherapy in the doctor–patient relationship itself, formal psychotherapy begins with Hippolyte Bernheim, professor of medicine at the University of Nancy in eastern France, in 1884, when Bernheim, in his book *On Suggestive Therapy under Hypnosis or in the Waking State* (*De la Suggestion dans l'État Hypnotique et dans l'État de Veille*) distinguished between hypnotic suggestion (which had been around for a century) and nonhypnotic suggestion, or a good talking-to. In 1904, Paul Dubois, professor of neuropathology in Berne, Switzerland, proposed "rational psychotherapy," a forerunner of today's cognitive-behavioral therapy (CBT), in his book The Psychoneuroses and Their Psychological Treatment (*Les Psychonévroses et leur Traitement Moral*). In 1903, Pierre Janet, professor of experimental psychology at the Sorbonne, proposed "psychasthenia" as the main mental disorder and advocated a kind of cathartic therapy for its treatment. These early systems were then overwhelmed by psychoanalysis, which by the 1920s had become the chief psychotherapy of psychiatry (see below), and were forgotten.

Psychoanalysis

Previous histories of psychiatry customarily gave great space to the history of psychoanalysis, or Freudian "depth psychiatry." Yet today, psychoanalysis has virtually disappeared from psychiatry, and such extended coverage seems pointless. For detailed accounts, the reader is referred to the author's own *History of Psychiatry* (1997) or to one of the frankly adulatory chronicles of Freud's life such as that by Peter Gay. In retrospect, psychoanalysis may be seen as a kind of hiatus in an ongoing current of biologic thinking in psychiatry that began with the old asylum physicians around the middle of the 19th century and revived with enthusiasm about drug treatments in the 1950s, resulting in the substantial displacement of psychoanalysis by psychopharmacology, neuroimaging, molecular genetics, and other

Telegram: @medical_k

www.konkur.in

forms of neuroscientific investigation in the 1970s. The following discussion is appropriately brief.

Psychoanalysis, a system of thought that attributes the origin of behavioral symptoms to conflicts within the unconscious mind, was originated by Vienna's Sigmund Freud in the late 19th century. Although *Studies in Hysteria*, the volume that Freud coauthored with Vienna family physician Josef Breuer in 1895, is commonly seen as the founding document of psychoanalysis, it merely presents psychiatry's most famous patient, "Anna O" (Bertha Pappenheim), in the context of abreactive therapies. Freud's seminal doctrines themselves come to blossom only in 1900 in The Interpretation of Dreams (*Die Traumdeutung*). In successive years, Freud slowly adumbrated the essentials of psychoanalytic treatment, explaining the role of the interpretation of dreams and of free association. Then in the early 1920s, Freud proceeded to trace the architecture of the psyche in the layers that he hypothesized: ego (conscious mind), superego (the source of morality, supposedly derived from oedipal fears toward the father), and the id (unconscious mind, harboring the sex drive and the death instinct).

Psychoanalysis as a movement began in 1902 when Freud founded a discussion group called the Psychological Wednesday Society, a group of curious physicians—many of them spa physicians and physiatrists in search of some kind of psychic bond to their patients. In 1908, this discussion group became the Vienna Psychoanalytic Society. In the same year, the first international congress of psychoanalysis took place in Salzburg, followed by a second congress in 1910 in Nuremberg, and a third in 1911, in Weimar. Meanwhile, the movement was plagued by schisms as early advocates such as Alfred Adler broke away, unable to accept Freud's doctrine of infant sexuality fully.

After the First World War, psychoanalysis became a major international movement. The dominant form of medical psychotherapy shifted from the former systems of Dubois and Janet to psychoanalysis. Psychoanalytic societies sprang up in the major western cities, and only with the Nazi seizure of power in 1933 (and Anschluss with Austria in 1938) was this expansion brutally braked.

Telegram: @medical_k

www.konkur.in

As the movement leached out of Europe, the United States, especially New York, Washington DC, and Los Angeles, became the world epicenter of psychoanalysis.

In the New World, under the influence of such émigé analysts as Hungarian-born Sandor Rado in New York, depressive neurosis began to loom in psychoanalysis. Freud himself had little interest in depression because the patients wanted mainly to be left alone and not tell their dreams or free associate. But in New York, “depressive neurosis,” or “neurotic depression,” started to become the meat-and-drink of the Park Avenue analysts, as opposed to “hysteria,” “phobic neurosis,” and the other diagnoses that Freud himself had placed front and center. In 1931, at the request of Abraham Brill, Rado helped organize training at the newly founded New York Psychoanalytic Institute. After a disagreement with other members, in 1945, Rado headed the newly opened Columbia University Psychoanalytic and Psychosomatic Clinic for Training and Research, the first training institute within a university.

Once psychoanalysis had drifted into exile, the movement began to break into rival camps, such as ego psychology (the classic drive-defense tradition as continued in Anna Freud’s 1936, *The Ego and the Mechanisms of Defense*); Donald Winnicott and Melanie Klein’s object relations theory; and self-psychology (associated in particular with Heinz Kohut’s book *The Analysis of Self* [1971]).

In object relations, Melanie Klein’s *The Psycho-Analysis of Children* (1932) highlights the importance of introjection and projection as mechanisms. As Klein’s biographer John Arnold Lindon explained, “Projection alters the infant’s impression of his environment, and by introjection this changed picture of his environment influences what goes on in his mind. Thus an inner world is built up that is partly a reflection of the external one.”

After the 1970s, psychoanalysis became less quarrelsome and drifted even further from Freud’s original emphasis on infantile sexuality. Psychodynamic psychiatry (which is not the same thing as psychodynamic psychotherapy) agrees on the importance of unconscious conflict, psychic determinism, the role of development, transference, counter-transference, and resistance. The field is no

Telegram: @medical_k

www.konkur.in

longer opposed to medication (analysts once scorned “pills” as a hindrance to getting at the “root causes” of the complaint). Glen Gabbard at Baylor College of Medicine in Houston writes in 2009,

> A patient with a bipolar disorder who is denying that he has an illness and refusing to take lithium may ultimately have better compliance with the medication if the clinician explores the meaning of his denial and his reluctance to consider himself as someone requiring treatment.

Yet, despite the efforts of psychoanalysts to integrate findings from psychopharmacology and the neurosciences, the wind has slowly gone out of the field. There had been a time when the chair of virtually every major department of psychiatry in the United States had been a psychoanalyst. But by 1990, more than 100 of 163 residency programs for psychiatry had abandoned instruction in intensive psychotherapy. The percent of psychiatrists who were also psychoanalysts declined from around 10% in the 1950s to 2.7% by 1988. What once was the very intellectual core of the discipline of psychiatry has become a marginalized group of enthusiasts. As Arthur Yuwiler, a senior biochemist in the Department of Psychiatry at the University of California, Los Angeles (UCLA), reflected somewhat ruefully in 2004, on the exchange of the psychoanalytic paradigm for the biologic one, “I seemed to spend the first half of my scientific life arguing with psychiatrists that there was a brain as well as a mind and the last half arguing there is a mind as well as a brain.”

Nonpsychoanalytic Psychotherapies

Formal systems of psychotherapy began with Hippolyte Bernheim, an internist in the French provincial medical school at Nancy, in 1884, with his distinction between hypnotic and nonhypnotic “suggestive” therapies: the latter meant, essentially a good chat. Bernheim believed hypnosis to be an effective treatment. Jean-Martin Charcot, in Paris, however, thought hypnotizability to be merely a diagnostic marker of “hysteria.”

Group psychotherapy began with Scottish psychiatrist William Alexander Francis Browne at the Crichton Royal Hospital in

Telegram: @medical_k

www.konkur.in

Dumfries in 1842 when he encouraged patients to stage amateur theatricals that amounted to a form of “mental therapeutics.” This strand was continued in 1922 in Vienna with Jakob Moreno-Lewy’s impromptu theater that was later tagged “psychodrama.” After Moreno immigrated to the United States in 1925, he introduced in 1931 group psychotherapy. Independent of Moreno, in these years, Louis Wender at Hillside Hospital and Paul Schilder at Bellevue Hospital, both institutions in New York, also began psychotherapy in groups. Closely related to group psychotherapy was the “therapeutic community,” which was birthed in England during the Second World War at the hands of Joshua Bierer and Thomas Main. (See section on social psychiatry.)

In the United States, the transition of psychotherapy from physicians to psychologists and psychiatric social workers began with psychologist Carl Rogers’ “client-centered therapy” after 1946. His book of that title appeared in 1951.

Family therapy is generally considered to have begun with Columbia University’s Nathan Ackerman at the founding in 1956 of the “family mental health clinic,” part of New York’s Jewish Family Service.

Social and Community Psychiatry

The main narrative arc in psychiatry is basically a first (19th-century) biologic psychiatry, then a psychoanalytic hiatus in the first half of the 20th century, followed by a second biologic psychiatry (late 20th century). Yet in the years 1940 to circa 1980, another current arose in psychiatry flowing separately from this main narrative stream: it was social and community psychiatry.

After the Second World War, the field became increasingly preoccupied with the social causation of illness and with group therapies for its treatment. A movement arose to treat patients in the context of the community rather than the asylum, and in 1946, D. Ewen Cameron, head of psychiatry at McGill University, created the first day hospital in the world at the Allan Memorial Institute in Montreal. In 1948, Joshua Bierer established the first in England, a

Telegram: @medical_k

www.konkur.in

"social club" at the Social Psychiatry Centre in London that he had founded two years previously. The movement incorporated, in 1959, Bierer's view that "Treatment must include the whole social environment of the patient and all his social relationships. He must be treated not only as a person but as part of a community." So influential did social psychiatry become in the United States that it influenced the removal of the National Institute of Mental Health (NIMH) in the years 1967 to 1992 from the National Institutes of Health, to protect, according to Joel Paris, head of psychiatry at McGill and author of *Fall of an Icon* (2005), "the social mission of the Institute from mainstream medicine." Many social psychiatrists also saw themselves as social reformers, on the grounds, as Paris continued, that "poverty and social disruption were the real causes of psychological symptoms." Therefore, "society, not the individual, should be the 'patient.'"

These ideas accorded well with the social activism of the mid-20th century. But as early as 1956, Ralph Gerard, a neuroscience leader at the University of Michigan, said presciently,

> We have all wished mental disease to be determined by sociological causes, because this situation seemed more hopeful from the therapeutic standpoint. The individual broken by the group could be healed by techniques of interpersonal interaction; but if he had bad genes, effective treatment was far in the future.

And indeed, in the United States, social psychiatry was rapidly eclipsed by mushrooming biologic perspectives.

Today, CBT is probably the most widespread form of medical psychotherapy and is associated with Philadelphia psychiatrist Aaron Beck from 1963. Popular as well is Interpersonal Psychotherapy, originated in 1967 by Yale psychiatrist Gerald Klerman and coworkers, especially for the treatment of depression. Also of interest is "dialectical behavior therapy" (DBT), a form of CBT emphasizing "mindful awareness," proposed by Marsha M. Linehan, a psychologist at the University of Washington, in 1999.

Yet while the number of psychotherapies proliferated, the percentage of psychiatric consultations in the United States that involved psychotherapy declined from 44.4% in 1996 to 1997 to

Telegram: @medical_k

www.konkur.in

28.9% in 2004 to 2005. Clearly, the single-office psychiatrist with a primarily psychotherapeutic practice, once the very image of psychiatry with its emphasis on “the couch” and “root causes,” was giving way to the health care team with the psychiatrist’s primary purpose being diagnosis and the provision of medication.

FROM ASYLUM TO UNIVERSITY

In the last quarter of the 19th century, many national medical bodies began demanding that psychiatry be included in the medical curriculum. This created a demand for professors of psychiatry and for academic centers in which to train them. As a result of this curricular development, research began shifting from asylums to university psychiatric hospitals and academic departments of psychiatry. Investigators in many of these centers came to dominate the field, and the asylums became research backwaters, increasingly given over to warehousing the ever-growing numbers of patients rather than treating them.

German-Speaking Europe

Said British psychiatrist Malcolm Lader in 1990, “We always used to say if you go back far enough and look at German literature at the turn of the century, you’re sure to find that someone described panic disorder and everything else.” It was the closeness of the link between the academy and the psychiatric hospital that granted this extraordinary German celerity in psychopathology; much of this architecture of the delineation of syndromes still remains. This leap from asylum to the academy in German-speaking Europe sped forward in 1874 when for the first time, university professors began taking part in the Association of Southwest German Alienists, hitherto a group of influential asylum psychiatrists.

Vienna. The capital of the Austro-Hungarian Empire, Vienna was a psychiatric super-power, the global influence of which was far disproportionate to the medium size of the city. The train of distinguished psychiatrists began in the late 18th century with such

Telegram: @medical_k

www.konkur.in

figures as Franz Joseph Gall (who first speculated about cerebral localization) and continued into the 19th with Ernst von Feuchtersleben, whose 1845 Textbook of Medical Psychiatry (*Lehrbuch der ärztlichen Seelenkunde*) popularized the term "psychopathy," in the sense of a disordered personality. (Feuchtersleben also distinguished between "neurosis" and "psychosis," giving them exactly the opposite meaning they were later to have.) But the modern tradition of Vienna as a bastion of biologic psychiatry (psychoanalysis came later) began with psychiatry professor Theodor Meynert ("MY-nert") with his great 1869 treatise on neuroanatomy, *The Architecture of the Cerebral Cortex (Der Bau der Gross-Hirnrinde)*, and continued with *Illnesses Involving the Forebrain in 1884 (Erkrankungen des Vorderhirns)*, which was completely forgotten midst later shrieks of jubilation about the importance of the frontal and prefrontal lobes in schizophrenia. His successor Richard von Krafft-Ebing is remembered for his textbook of sexology Psychopathia Sexualis (1886); his successor, in turn, Julius Wagner von Jauregg ("YOW-reg"), introduced in 1917, the malarial fever cure, an epochal accomplishment for which he received the Nobel Prize in 1927. Aside from the professors, Josef Berze, head of the Vienna city asylum "Am Steinhof," described "primary insufficiency of psychic activity" in schizophrenia in 1914, and Constantin von Economo, who led a brain research institute, reported the new disease of "encephalitis lethargica" in 1917. It was in the years following 1930 that Manfred Sakel proposed insulin coma therapy (while still in Berlin; only in 1933 did Sakel return to Vienna to conduct clinical trials—see below). Finally, pediatrician Hans Asperger described "autistic psychopathy" in 1944, among the earliest descriptions of autism (which was first used as a term in pediatric psychiatry by German and Russian neurologists and psychiatrists early in the 1920s). Vienna's contribution to psychoanalysis would begin in 1900, with the publication of Sigmund Freud's *Interpretation of Dreams* (see above), and continue until the expulsion or murder of the Jewish psychoanalysts in 1938 after Anschluss with Germany. After the Second World War, Vienna never again regained this historic preeminence in psychiatry.

Telegram: @medical_k

www.konkur.in

Heidelberg. The flagship of academic psychiatry in the German Empire berthed in Heidelberg. The "Psychiatric-Neurological Clinic" of the University ("Klinik" in German means university hospital) was founded in 1879 by Otto Fürstner; it was the first university psychiatric department with beds of its own so that patients didn't have to be brought from a nearby asylum for demonstration in clinical lectures. Its most distinguished head was Emil Kraepelin, who had the professorship from 1891 to 1903, during which time the crucial editions of his textbook appeared (see below). The Klinik was also a provincial asylum with a catchment basin of its own. When Kraepelin left for Munich, the professorship was assumed by neuropathologist Franz Nissl, known for his demonstration in cells of the "Nissl substance." At various points, Kraepelin's Klinik served Alois Alzheimer (who followed Kraepelin to Munich) and Karl Jaspers. In the 1920s, such important figures as Willi Mayer-Gross (who after fleeing the Nazis to England coauthored the standard English psychiatry textbook, *Clinical Psychiatry*, in 1954); Carl Wilmanns (pioneering studies of the homeless); Hans Gruhle (premier schizophrenia researcher of his day); and August Homburger (who founded in Germany modern pediatric psychiatry). This wall of scholarship crumbled in 1933, and the names of the successors under the Nazis are either forgotten or live on in infamy. Heinz Lehmann later said in retrospect, "German medicine was an impressive thing and there is no doubt about it. When we all went away, I don't think this tradition was transferred to America but it was abolished in Germany."

Berlin. In 1795, a psychiatry department was founded in the Charité, the Prussian state's great military hospital, and in 1806 Ernst Horn was called to become associate director of the hospital, with simultaneous responsibility for psychiatry. Under Horn, psychiatry at the Charité conformed to the concepts of the day of a proper reformed asylum, though Horn was much assailed for some of his practices and left under a cloud in 1818. Ten years later, he was succeeded by Carl W. Ideler, one of the so-called "Romantic" psychiatrists who saw illness as evidence of sin. This unhappy

Telegram: @medical_k

www.konkur.in

period came to an end with Ideler's death in 1860 and Wilhelm Griesinger's arrival in 1865 to convert the old psychiatric ward into a modern neuropsychiatric clinic (Klinik für Geistes- und Nervenkrankheiten). In 1867, Griesinger founded the lead German journal for biologic psychiatry, the *Archive for Psychiatric and Neurological Diseases* (*Archiv für Psychiatrie und Nervenkrankheiten*, of which the current *Archives of General Psychiatry*—now called *JAMA Psychiatry* is a distant echo). Griesinger died prematurely in 1868 of acute appendicitis. Following Griesinger came a distinguished series of biologically oriented psychiatrists, including Carl-Friedrich Westphal in 1869 (who in 1872 described agoraphobia and in 1877 obsessive-compulsive disorder). His tenure ended with his death in 1890 of what seems to have been neurosyphilis—of which so many middle-class men perished in those days (infected as medical students or law students with primary syphilis from prostitutes). Karl Bonhoeffer had the Berlin chair from 1912 to his emeriting in 1937, after which another grim period began in the history of German psychiatry. In 1909, Bonhoeffer conceived the notion of "exogenous psychosis," arising from stress or toxins from outside rather than being endogenous and inborn.

In a separate development, in 1902, Oskar Vogt founded a neurobiologic institute at the University, which in 1915 was joined with the Kaiser-Wilhelm-Institute for Brain Research. (His wife, the French-born Cécile Vogt, became an important neuroscientist, later settling in England. Their daughter Marthe discovered in 1965 that noradrenalin was present in the brain.) In 1931, the institute was transferred to the Berlin-Buch mental hospital and came in 1937, under the direction of Hugo Spatz, who was a member of the Nazi party but who goes down in history as co-discoverer of the Hallervorden–Spatz disease of neurodegeneration. Despite its vicarious history, this institute became one of the world's leading neuroscience centers.

Munich. When in 1903, Kraepelin went from Berlin to Munich, it was as the inaugural director of a newly built University Psychiatric Hospital in the Nussbaumstrasse. He proceeded to make it into a

Telegram: @medical_k

www.konkur.in

world-class institution, bringing, as stated, Alois Alzheimer from Heidelberg to head the pathology laboratory, to which young investigators streamed from all over the world.

In 1917, Kraepelin founded a freestanding psychiatric research institute, the Kaiser-Wilhelm-Institut für Psychiatrie. The psychiatric department of the adjacent Schwabing City-Hospital, headed after 1931 by Kurt Schneider, became its clinical arm. Slow to get off the ground, the Institute's take-off began only in the mid-1920s, thanks to a group of foreign donors led by James Loeb (after whom a street in front of the present institute is now named). In 1917, Ernst Rüdin became head of the "genealogic-demographic" (genetics) section (see below). The scientific promise of the Institute was nipped in the bud by the Nazi takeover, and only after the war, when in 1954 it became the Max Planck Institut für Psychiatrie, did its international reputation blossom.

Zurich. In Zurich, a city psychiatric hospital was founded in 1860, and when Wilhelm Griesinger began lecturing there in 1863, it became a "Klinik." Two years later, in 1865, Griesinger decamped for Berlin. In 1869, a grand new Klinik was planned at a spot called the "Burghölzli"; the "Bli," as it was known, was helmed over the years by some important figures, including Auguste Forel (1898–1927), a co-originator of the "neuron theory" of cerebral communication; Eugen Bleuler (1898–1927), who coined the term "schizophrenia"; and his son Manfred Bleuler (1942–1969), who in 1954, determined that the prognosis of schizophrenia was often benign.

France

Paris is the great focus of French psychiatry, and in Paris, each of the main general hospitals had academic psychiatry departments chaired by professors. Yet in addition, Paris had one special institution not found elsewhere in France (or in other lands, for that matter): The special psychiatric reception service of the Prefecture of Police (la Infirmérie Spéciale des Aliénés de la Préfecture de Police).

Telegram: @medical_k

www.konkur.in

In 1800, Paris was given a special prefect for police, and with the general mental patients law of 1838, this prefect acquired responsibility for mental patients who came to public attention. Seven years later, in 1845, this special reception service became headed by a psychiatrist. From this service flowed a good deal of the research of modern French psychiatry. The first head of note was Ernest-Charles Lasègue in 1850, who coined the diagnostic term “delusions of persecution” in 1852, and “hysterical anorexia” (anorexia nervosa) in 1873. (Lasègue also had a series of academic appointments in the teaching hospitals.) In 1872, the Infirmérie Spéciale became independent of the police headquarters and turned into an important center for research. Following his death in 1883, Lasègue was succeeded by his assistant Henri Legrand du Saulle, who in 1875 offered an early description of obsessive-compulsive disorder (*la folie du doute avec délire du toucher*).

At the Salpêtrière hospice in 1882, Jean-Martin Charcot became the inaugural holder of a chair in nervous diseases, created especially for him by the president of the Republic. Charcot’s contributions lay mainly in neurology, but his name is indissolubly connected with a certain kind of “hysteria,” involving supposed chronic stigmata and elaborate acute pantomimes that in retrospect were phenomena of suggestion and that disappeared after his death in 1893. Among the students of Charcot, best known is Joseph Babinski, who in 1896 described the plantar extension reflex that is named after him. Charcot’s successors Fulgence Raymond and Jules-Joseph Dejerine were better known as neurologists than psychiatrists.

The “clinical asylum” Sainte-Anne was opened in 1867 as the asylum of the Seine department, with Valentin Magnan, the notable advocate of “degeneration” theories, as director of its admissions department. In 1877, Benjamin Ball became the inaugural holder of the Chair of Mental and Brain Disease. Among his successors were Henri Claude in 1922, an early biologic psychiatrist, and Jean Delay in 1946, who introduced the psychopharmacological era in France. The facility became a “psychiatric hospital” in 1937, a “psychiatric

Telegram: @medical_k

www.konkur.in

center" in 1944, and a "hospital center" (shedding the unfashionable adjective "psychiatric" entirely) in 1974.

United Kingdom

London. In 1908, the asylums committee of the London County Council accepted a gift from psychiatrist Henry Maudsley to found a research hospital based on the model of the German university psychiatric clinic. The war interfered with the realization of these plans, but in 1923, the Maudsley Hospital opened its doors for psychiatry with Edward Mapother, its inaugural superintendent. The Maudsley was not to be an asylum. Mapother made clear, as historian Edgar Jones relates (in a 2003 article in Medical History), "that no patient was to be admitted under section, nor would they be certified once in the hospital." Mapother had an academic appointment at King's College Hospital and wanted to make the Maudsley the psychiatric arm of the college's teaching. (Mapother received the title "professor" in 1936.) Aubrey Lewis, who joined the staff in 1928, becoming a medical officer in 1936, recalled, "The place was small, full of ambition and energy, but everybody was overworked." In 1946, Lewis was appointed professor of psychiatry, and two years later, in 1948, the teaching unit at the Maudsley was renamed Institute of Psychiatry (IOP). In that year as well the Maudsley merged with the Bethlem Royal Hospital (the former "Bedlam"). Lewis began adding Medical Research Council (MRC) units; the first of these, the MRC Social Psychiatry Unit under Lewis himself opening in 1948. These helped make the Maudsley the premier institution in the United Kingdom for research in psychiatry. In 1997, the IOP split from the Maudsley to become a school of King's College London. The Maudsley was a major font of social psychiatry in the United Kingdom. Psychiatrist David Healy recalled that Aubrey Lewis had stated, at a meeting in 1958 (in Healy's words), "'If we had a choice between the new drugs and the social treatments, such as industrial rehabilitation units, we would pick social treatments.' And it's interesting that in the UK under Lewis' influence, the Maudsley remained very aloof from the new drugs."

Telegram: @medical_k

www.konkur.in

Accordingly, the first center of research for psychopharmacology in the United Kingdom—the first anywhere—was the Department of Experimental Psychiatry, founded by Joel Elkes at Birmingham in 1951. It was here that some of the earliest trials of the antipsychotic chlorpromazine were conducted. “I felt like a naturalist advancing into a strange continent,” said Elkes later. The notion that drugs, as opposed to psychotherapy, could prove curative in psychiatry was then very new.

On Scotland and Ireland (See in Early Beginnings Section)

Canada—McGill University

Canada contained one of the most internationally important departments of psychiatry at McGill University in Montreal. The Department of Psychiatry of McGill was the Allan Memorial Institute (named after a donor), founded in 1940 at the instigation of neurosurgeon Wilder Penfield. Chaired by D. Ewen Cameron from 1943 to 1964, it was under Cameron that the “Allan” became one of the most distinguished psychiatry departments in North America. Its clinicians and scientists included psychoanalyst Miguel Prados, who arrived from Spain in 1944; the neuropathologist Karl Stern who in 1944, established a gerontologic unit, the first in the world; the neuropathologist Vojtech Adalbert Kral, a Holocaust refugee who arrived at the Allan in 1953 and pioneered research in dementia; Clifford Scott, who became an international leader of psychoanalysis, arrived from the Maudsley in 1954. (One wag said, “Kral felt if you couldn’t see it, it didn’t exist and Clifford Scott … felt if you could say it, it wasn’t important.”)

Included as well were: Neurophysiologist Robert Cleghorn in 1946, who pioneered endocrinologic psychiatry; Charles Shagass in 1950, who conceived the notion of the “sedation threshold”; Eric Wittkower, who in 1955 set up the section on transcultural psychiatry as a joint venture with the department of anthropology; Wittkower recruited Henry BM Murphy, author of the standard textbook of transcultural psychiatry (Comparative Psychiatry, 1982), who became head of the

Telegram: @medical_k

www.konkur.in

section in 1965 after Wittkower retired; and Heinz Lehmann, who came to Montreal in 1947 as director of the Verdun Protestant Hospital and is considered one of the founders of psychopharmacology. (The World Health Organization's first training center for psychopharmacology was at the Douglas.) Psychiatrist George Simpson, a first-year resident at McGill in 1956, later said in an interview, "I would argue that the Allan was the most stimulating place in the English-speaking world at that moment, even though the rest of the city spoke French."

United States

After the Second World War, the United States came to dominate world psychiatry, partly as a function of the torrent of research funds from NIMH, partly as a result of the Diagnostic and Statistical Manual of the American Psychiatric Association becoming after 1980, the world bible of psychiatry. The Holocaust and the devastation of the Second World War also had a great deal to do with the new American primacy. Rather than flocking to the Maudsley or Vienna for training, as budding American psychiatrists did before the war, it was young psychiatrists from all over the globe who sought further training in the United States. This new American hegemony accounts for the length of the following section.

New York. New York held the greatest concentration of psychiatric firepower in the United States owing to a series of public and private teaching hospitals.

HILLSIDE HOSPITAL. Hillside Hospital, initially in Hastings-on-Hudson, was founded by Israel Strauss in 1927 as a charitable Jewish hospital operated in a nonsectarian manner. In 1941, the hospital removed to Glen Oaks, Queens. It was, as Strauss put it, "the first institution of its kind for Jews in this country." Hillside specialized in "borderline" cases, meaning the kind of psychoneurosis that usually would not receive in-patient treatment. In 1930, Louis Wender, chief physician, began one of the first programs of group psychotherapy in the country. In the 1940s, Hillside was among the earliest U.S.

Telegram: @medical_k

www.konkur.in

institutions to offer the various shock therapies. Although mainly psychoanalytic in inspiration, in 1950, Hillside resolved upon a "biochemical" research program, and in 1952 hired Max Fink to establish the Department of Experimental Psychiatry, which was joined by Donald Klein in 1957. Fink and colleagues set up an electroencephalogram (EEG) laboratory in 1953, and with Klein, conducted pioneering trials in psychopharmacology. By 1999, following several mergers, what had become Zucker Hillside Hospital was merged into the North Shore Long Island Jewish Health System, which encompassed seventeen hospital systems.

NEW YORK/PRESBYTERIAN/WESTCHESTER DIVISION. The foundation and growth of the New York Hospital, the second oldest freestanding psychiatric hospital in the United States, is discussed above. In 1898, the hospital became associated with Weill Cornell Medical College as that institution was founded, and a 1927 endowment lent to the psychiatric division the title Payne Whitney Psychiatric Clinic. New York Hospital merged with Presbyterian Hospital in 1996, and the Payne-Whitney Clinic was renamed the New York/Presbyterian Westchester Division.

NEW YORK STATE PSYCHIATRIC INSTITUTE. In 1896, the New York State Pathological Institute was established in New York City under Ira Van Gieson. It was the first effort in the state to study the anatomical basis of insanity, receiving specimens from the various state hospitals. In 1904, the Swiss-born Adolf Meyer, previously a pathologist at several state hospitals and a professor at Clark University, succeeded him. Meyer was already a significant scientific figure and would go on in 1910 to become a professor of psychiatry at Johns Hopkins University and inaugural head of the Henry Phipps Psychiatric Clinic (see below). In 1902, the Pathological Institute moved to Ward's Island next to the Manhattan State Hospital. Meyer changed the name to Psychiatric Institute in 1907. Following a fire at Manhattan State, planning began to convert the institute to a state mental health research hospital and to situate it at Washington Heights, where Columbia was building a new medical school, and

Telegram: @medical_k

www.konkur.in

Presbyterian Hospital was to move. The new building of the now New York State Psychiatric Institute was dedicated in December 1929. Known as "PI," it became the psychiatry department of Columbia University as well offering from 1931 a 10-week course for psychiatrists in the New York State Mental Hospital system. In 1936, Nolan DC Lewis, professor of neurology in the Neurological Institute, became the first academic to lead PI. He, in turn, was followed by Lawrence C. Kolb in 1954. The Psychiatric Institute innovated at all points on the treatment spectrum: In 1942, a Department of Research Psychiatry was created, with Eugene Barrera and Bernard Pacella, its main members. In 1945, a Psychoanalytic Center for Training and Research was founded, the first official psychiatric training institute to be established in a medical school. Despite the massive interest at PI in psychoanalysis, early in the 1950s, a small number of investigators led by Philip Polatin became involved in psychopharmaceutical trials; by 1956, the Institute had a department of experimental psychiatry, now led by Sidney Malitz, located at the Vanderbilt Clinic.

PI benefited greatly from the tumult of the century, giving refuge to many distinguished scientists and clinicians fleeing the Holocaust. Among the members of the informal "European Club" were Lothar Kalinowsky (from Germany and Italy), the padrone of electroconvulsive therapy (ECT) in the United States; neurochemist Heinrich B. Waelsch (Prague); Paul Hoch (Hungary and Germany), who headed experimental psychiatry and coined the diagnosis "pseudoneurotic schizophrenia"; Sandor Rado (Hungary) who became a leader of psychoanalysis in the New World; Armando Ferraro (Italy), who headed neuropathology at PI. Eric Kandel, who established the Center for Neurobiology and Behavior in 1974, was born in Vienna and later (2000) won a Nobel Prize.

The East Coast

WASHINGTON DC: THE NATIONAL INSTITUTE OF MENTAL HEALTH. The NIMH, funded by the federal government as one of the National Institutes of Health, is not a degree-granting institution, but it is very

Telegram: @medical_k

www.konkur.in

academic, encouraging original research both in-house, in the "intramural program," and by funding "extramural" psychiatric research across North America. The involvement of the federal government with psychiatric research began in 1929 with the founding of the Narcotics Division of the Public Health Service, renamed Division of Mental Hygiene in 1930. Lawrence Kolb became the chief PHS officer in charge of the division of mental hygiene, and on his retirement in 1944, he had wished to set up a national neuropsychiatric institute (NPI) within the National Institute of Health (NIH). This became possible in 1946 when the National Mental Health Act called for the creation of a National Institute of Mental Health with an in-house research program. NIMH opened its doors in 1949, and Robert Felix, who had succeeded Kolb as director of mental hygiene, became the institute's inaugural director in 1951, with physiologist Seymour Kety in charge of research.

In 1953, the first clinical NIMH ward opened at the Clinical Center for the NIH; there followed in 1955 the Laboratory of Clinical Science and in 1956 the Psychopharmacology Service Center, which in 1960 organized the Early Clinical Drug Evaluation Program, Jonathan Cole, its director. The program became a great engine of progress, conducting investigational trials in the 35 Early Clinical Drug Evaluation Units (ECDEUs) that came to be established by 1969. By 1982, among the 100 investigators most frequently cited in scientific research worldwide, 9 were in the NIMH intramural program.

JOHNS HOPKINS UNIVERSITY: THE PHIPPS PSYCHIATRIC CLINIC. Psychiatry at Johns Hopkins began in 1910 when Adolf Meyer was hired from the Pathological (later Psychiatric) Institute of the New York State Hospitals to become the inaugural professor of psychiatry and director of the new university psychiatric hospital, the Phipps Clinic, funded by Henry Phipps, which opened its doors in 1913. On his retirement in 1941, Meyer was succeeded by Nebraskan John Whitehorn in office until 1960. In these years, Rockefeller Foundation grants brought many young European psychiatrists to the Phipps to study, and it was through them that Meyer's international influence became considerable.

Telegram: @medical_k

www.konkur.in

MCLEAN HOSPITAL (CONTINUED FROM ABOVE). In 1888, profiting from the scientific boom then sweeping U.S. psychiatry, a pathology department was organized at the McLean asylum. In 1895, the institution removed from Charlestown to Waverley (Belmont), a suburb of Boston, and was named McLean Hospital. Swiss-born August Hoch, who would shortly study with Kraepelin and Alzheimer, became leader of a chemical laboratory in 1893; Hoch became an early advocate of the new neurohistopathology; a psychology laboratory followed in 1904. After 1955, in keeping with the changing times, the hospital pioneered in the U.S. concepts of the therapeutic community under Alfred H. Stanton.

But biology lay waiting. In 1972, the "transformation of McLean," as Alan Schatzberg later put it, began when Shervert Frazier, who had also qualified as an internist, came up from Columbia University to become a director. He recruited psychotherapist John Gunderson in 1973, who became the "borderline" specialist; Jonathan Cole and Schatzberg came in 1974 to work in depression; there arrived as well from Massachusetts General Hospital (the parent organization), Joseph Lipinsky in 1974, and Seymour Kety and Ross Baldessarini in 1977. Schatzberg said, "He recruited outstanding people and built the Mailman Research Center, an unbelievably vibrant place."

HARVARD UNIVERSITY. The Department of Psychiatry at Harvard was founded in 1920 when Adolf Meyer's student, the Scottish-born Charles Macfie Campbell, left the Phipps Clinic in Baltimore to become director of the Boston Psychopathic Hospital and the inaugural professor of psychiatry at Harvard. Like his mentor, Campbell leaned toward "psychobiology" and psychoanalysis. The influential post at Harvard, however, is chief of psychiatry at the Massachusetts General Hospital, one of Harvard's teaching hospitals (of which McLean was administratively a part). This post was initially held in 1934 by Stanley Cobb, professor of neuropathology and previously director of the Harvard Neurological Unit at the Boston City Hospital. Some consider Cobb the founder of biologic approaches to psychiatry in the United States. Among

Telegram: @medical_k

www.konkur.in

Cobb's successors were Erich Lindemann in 1955, John Nemiah in 1965, and Leon Eisenberg in 1967.

THE INSTITUTE OF LIVING (CONTINUED FROM ABOVE). In 1931, when C. Charles Burlingame was appointed superintendent, what was then the Neuropsychiatric Institute of the Hartford Retreat was in a downhill slide. Burlingame effected a revival, establishing a school of nursing, bringing in recognized figures on staff (to regain the lost accreditation), and, later in the 1930s, implementing the new "shock" therapies. In 1943, the name was changed to the Institute of Living. In 1946, Francis J. Braceland, who had studied at the Zurich University Psychiatric Hospital and the National Hospital for Nervous Diseases in London, became chief psychiatrist. (Braceland is also remembered for being a special witness at the Nuremberg Trials in 1946, whose testimony saved Rudolph Hess from execution.) Said a New York Times obituary in 1985, Braceland is "credited with changing its reputation [Institute of Living] from that of a plush sanitarium for the rich and famous to that of a highly respected psychiatric hospital for the seriously ill." In 1994, the Institute of Living became part of Hartford Hospital.

YALE UNIVERSITY. Yale had the third university department of psychiatry in the United States—after Johns Hopkins and Harvard. The central figure here was Dean Milton C. Winternitz, a neuropathologist who conceived the Institute for Human Relations, which opened in 1931. (The department of psychiatry was situated in the Institute.) Winternitz said in 1925 of the proposed Institute, "… All of these disciplines primarily interested in the problems of human behavior from the standpoint of investigation, graduate teaching, and application, i.e., therapy, [should] be brought together geographically in a single building designed to allow the greatest possible latitude for … cooperation." An embryo department of psychiatry had come to life in the 1920s. Yet only in 1930 was it led by a significant figure, when Eugen Kahn, a Kraepelin student, and collaborator with Ernst Rüdin in schizophrenia genetics, became chair and the first Stirling

Telegram: @medical_k

www.konkur.in

Professor in psychiatry. He was followed in 1950 by another eminent Central European, Vienna's Friedrich ("Fritz") Redlich.

In 1911, Arnold Gesell created the Child Study Center at Yale, later associated with several departments, including psychiatry.

Elsewhere

CHICAGO. Chicago had a long tradition of contributions to psychiatry. In 1925, physiologist Nathaniel Kleitman organized a sleep laboratory at the University of Chicago, and from this lab emerged in 1953 a classic paper in Science co-written by Kleitman's student Eugene Aserinsky on rapid eye movement (REM) sleep. Neurologist and psychiatrist Percival Bailey had cofounded in 1946 the Society of Biological Psychiatry. And Laszlo von Meduna, the originator of convulsive therapy, arrived in Chicago from Budapest in 1939 and ultimately found a berth at the NPI of the University of Illinois.

Yet the founding figure in psychiatry is Roy Richard Grinker, who had a background both in psychoanalysis (worked with Freud in Vienna in the early 1930s) and in neurology. Grinker's career at the University of Chicago began in 1933, with his appointment as associate professor of neurology; he became associate professor of psychiatry in 1936, which established psychiatry within the department of medicine (Grinker's appointment at Michael Reese Hospital in 1936 is recalled as "taking over the department of neurology"). In 1955, psychiatry changed to a department in its own right, its first chair C Knight Aldrich. Although psychodynamics was then the watchword in Chicago, the University was not hesitant to appoint in 1966 the elfin Daniel X. Freedman from Yale as the next chair. Freedman, an enthusiastic promoter of biologic psychiatry, became chief editor of the AMA's Archives of General Psychiatry in 1970. He was succeeded as chair by Stuart C. Yudofsky in 1988 and Elliot S. Gershon in 1998. Steven Paul, who later led neuroscience research at Eli Lilly, recalled in a 2011 interview his years in the mid-1970s as a resident in psychiatry at the University of Chicago, "It was a very exciting department in those days. Herb Meltzer [biologic

Telegram: @medical_k

www.konkur.in

psychiatrist] was there and Heinz Kohut, the analyst, Bob Schuster [Charles R. Schuster, who founded the University of Chicago's Drug Abuse Research Center], and many others. A tremendous department Danny had pulled together, a small but extraordinarily fine department." Meanwhile, in 1974 Philip Holzman, professor of psychology at the University of Chicago, reported a major biologic abnormality in schizophrenia, saccadic eye-tracking movements (smooth-pursuit in tracking is normal).

UNIVERSITY OF NORTH CAROLINA. The Department of Psychiatry at the University of North Carolina (UNC) at Chapel Hill was founded by Chicago psychoanalyst George Ham in 1951. It started to become a biologic piston with the arrival in 1954 of Scotsman John Ewing as clinical instructor, then chair in 1962. Psychiatric endocrinologist Morris Lipton from the University of Chicago joined the department in 1959 and proceeded to steer it toward the endocrinologic hormones that science was just discovering. (Lipton became known as having "opened up the peptides.") Arthur Prange, who had trained at UNC, joined the staff in 1960 and proceeded to solidify UNC's growing association with psychiatric endocrinology. William McKinney (later at the University of Wisconsin) trained at UNC in the mid-1960s, and in his class were Frederick Goodwin (later an NIMH star), the Englishman Peter Whybrow (later chair of psychiatry at the UCLA NPI), and Joseph Mendels (who ended up leading biologic psychiatry at the University of Pennsylvania).

DUKE UNIVERSITY. Across the way from UNC lay Duke University in Durham. In 1953, Ewald Busse, psychoanalyst and geriatrician, became the founding chair of psychiatry at Duke. His successors H. Keith Brodie (1974 to 1982) and Bernard Carroll (1983 to 1990), ended this Freudian spin (in 1968, Australian-born Carroll introduced the dexamethasone suppression test [DST] into psychiatry for the diagnosis of melancholic depression). Duke and UNC together constituted a powerful core of psychiatric research for the southeast.

Telegram: @medical_k

www.konkur.in

UNIVERSITY OF PENNSYLVANIA. Psychiatry at the University of Pennsylvania had begun in 1793, when Benjamin Rush, a professor of chemistry, opened a ward for insane patients at Pennsylvania Hospital. But academic psychiatry at Penn really began only in 1874, with the establishment of the Hospital of the University of Pennsylvania. A department of mental diseases received its inaugural head in 1883, and in 1901, Charles Burr was appointed Penn's first chair of mental diseases.

Karl Rickels founded the Clinical Psychopharmacology Unit in 1959. And the Center for Mental Health Policy and Services Research (CMHPSR) was established in 1986.

THE "PSYCHOPATHIC HOSPITALS". Emblematic of the new association between asylum and academy were the so-called "psychopathic hospitals," which began life in the 1880s as reception wards for newly admitted, or "acute," patients. American psychiatrists visiting Europe had learned much about humane care and the usefulness of setting these acutely ill patients aside from the chronic patients working in the farm colonies or vegetating in the back wards. (Indeed, the spotlight began to turn toward creating psychiatric wards in general hospitals, such as "Pavilion F," founded in 1902, of Albany Hospital.)

In 1901, the Michigan legislature appropriated a sum for the establishment of a "psychopathic hospital" on the grounds of the State University of Michigan, as an additional ward of the University Hospital. It was not part of the state asylum system and was entirely under the control of the university. The psychopathic hospital did not, in fact, open until 1906, under the direction of neuropathologist Albert M. Barrett.

In Massachusetts in 1912, a psychopathic hospital opened on Fenwood Road in Boston as a department of the Boston State Hospital in Dorchester; it was under Elmer E. Southard, a professor of neuropathology at Harvard. The plan was, as Henry Hurd in his great 1916 work *The Institutional Care of the Insane* put it, to establish "a hospital for the first care and observation of mental patients and the treatment of acute and curable mental diseases and

Telegram: @medical_k

www.konkur.in

for an out-patient department … for scientific research as to the nature, causes and results of insanity." The patients were given laboratory tests, stabilized with hydrotherapy, and then either discharged as recovered or forwarded to the main wards of the state hospital. In 1920, the institution was renamed Boston Psychopathic Hospital under C. Macfie Campbell. In 1956, the name was changed again to Massachusetts Mental Health Center. Several prominent figures in U.S. psychiatry served there, including Abraham Myerson.

Fourteen further psychopathic hospitals were founded by the First World War, although their missions ranged from the conduct of research, as at the University of Michigan and Harvard's Boston Psychopathic, to the mere reception and detention of acute patients. (On the Iowa Psychopathic Hospital, opened in 1921, see below.)

Mississippi Valley Psychiatry. A string of important psychiatry departments ran down the Mississippi valley and played a crucial role in bringing the new biologic psychiatry to the United States.

UNIVERSITY OF IOWA. Academic psychiatry began in Iowa City with the opening of the Iowa State Psychopathic Hospital in 1921 under the state board of education. The director was simultaneously chair of psychiatry at the university, and the Iowa Psychopathic is considered the first university-affiliated psychiatric department west of the Mississippi. Under the founding director, Samuel T. Orton, in 1919, a neuropathologist who previously had been clinical director of the Worcester State Hospital in Massachusetts, the department rose to become one of the powerhouses of U.S. psychiatry. Jacques Gottlieb, whose background was in neuroendocrinology and who established the effectiveness of the amphetamines in the treatment of depression, taught at the Psychopathic Hospital from 1937 to 1940, then returned to Iowa as professor of psychiatry from 1947 to 1953 before moving on. Erich Lindemann came from Heidelberg to train at Iowa in 1927 and was on staff until 1935, before accepting a post at Harvard. While at Iowa, Lindemann was among the first to investigate the effects of psychopharmaceuticals. (Lindemann is also remembered for helping pioneer the diagnosis of traumatic stress

Telegram: @medical_k

www.konkur.in

with his 1944 study of “acute grief” in the survivors of the Cocoanut Grove Fire in 1942 in Boston.) Establishing a strong bridge between Iowa and Washington University in St. Louis, George Winokur came from Wash U in 1971 to chair psychiatry at Iowa. William Coryell followed in 1977. Ming Tsuang trained in psychiatry at Iowa then served as professor from 1975 to 1982. In 1996, Winokur and Tsuang (who by now had become the Stanley Cobb Professor of Psychiatry at Harvard) published *The Natural History of Mania, Depression, and Schizophrenia*, based on the research panel “the Iowa 500.” In 1971, Nancy Andreasen completed her training at Iowa, then, while on staff, went on to pioneer the neuroimaging of schizophrenia.

WASHINGTON UNIVERSITY IN ST. LOUIS. Psychiatry at “Wash U” began in 1918, under Sidney Schwab, who headed the division of neurology and psychiatry, a “subdepartment” of the Department of Medicine. In 1938, the Department of Neuropsychiatry became an independent unit under David M. Rioch, who passed the torch to Edwin Gildea in 1942. In 1948, Harvard-trained Eli Robins became a fellow at Wash U, joining the department in 1951. Meanwhile, in 1950 Samuel Guze joined the department, and for the next 20 years, the names Robins and Guze would be closely associated with the growth of psychiatry at Wash U as it became the premier department of biologic psychiatry in the United States. In 1970, they suggested the “medical model” as an alternative to the “biopsychosocial model,” as a motor for delineating disease.

Wash U was also one of the two seedbeds (Columbia the other) of the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders* (DSM). Recalled Paula Clayton in an interview, who at the time was a resident, “We all read Kraepelin. He was our bible.” Under Eli Robins (chair 1963 to 1975) and Samuel Guze (“Goo-zay,” chair 1975 to 1989), psychiatry at Wash U opened up a series of links between basic biology and clinical psychiatry. “[It] was nearer to being a mini-NIMH,” said geneticist Irving Gottesman later, “where under one roof you could have MDs and PhDs of all sorts working together on projects.” Graduates of Wash U assumed

Telegram: @medical_k

www.konkur.in

important leadership roles throughout U.S. psychiatry. It was the consummate insiders' group and displaced the previous insiders' group, the psychoanalytically oriented Group for the Advancement of Psychiatry (GAP).

Tennessee. Frank H. Luton became the first psychiatrist at Vanderbilt in Nashville, Tennessee, when he returned in 1931, after training at Johns Hopkins under Adolf Meyer. The School of Medicine created a department of psychiatry in 1947 with the appointment of William F. Orr, Jr, who in turn was succeeded by Marc Hollender in 1969, and Michael H. Ebert in 1983. Interest at Vanderbilt passed from dynamic psychiatry to psychopharmacology in the 1970s, with the appointment of such investigators as Fridolin Sulser, Thomas Ban, and Herbert Meltzer.

Meanwhile, in Memphis, Hagop Akiskal, a graduate in 1969 of the medical school of the American University of Beirut, had organized in 1973 an affective disease clinic at the University of Tennessee, one of the first in the United States. From 1987, Akiskal propagated the idea of a "soft bipolar spectrum," heavily dependent on temperament and managed with mood stabilizers rather than conventional "antidepressants."

Tulane. Psychiatry at Tulane in New Orleans was founded by Robert G. Heath after he arrived from Columbia in 1949. In New York, Heath had trained in both neurology and psychoanalysis and established a psychoanalysis program at Tulane. But his real interest lay in the possible metabolic origins of schizophrenia. The charismatic Heath, whom Time magazine called "the Gregory Peck of psychiatry," set out to investigate intracerebral events by persuading doubtful colleagues of the wisdom of inserting indwelling electrodes. This controversial program came to nothing, but Health had several important students. In 1960, one of them, Donald M. Gallant, won for the department of psychiatry a federal grant from the ECDEU of the National Institute of Mental Health, a program that aided the introduction of psychopharmacology into American psychiatry (see above). Gallant became chair in 1969 following

Telegram: @medical_k

www.konkur.in

Heath and expanded the entire range of research in psychopharmacology so that it became the flagship program of the Deep South in this area.

The West Coast. Several departments of international distinction on the West Coast were founded—much later than those in other parts of the country. Yet, they are part of the story of the transition from asylum to university psychiatric hospital.

STANFORD UNIVERSITY, PALO ALTO. Psychiatry at Stanford was founded in 1933 when George S. Johnson came from his post at the University of Colorado to become chair of neuropsychiatry. In 1954, neurology split from psychiatry, and Johnson continued as chair of psychiatry. Child and adolescent psychiatry, which was established in 1939, merged with the department in 1957. In 1960, Stanford University School of Medicine moved from San Francisco to Palo Alto, where it quickly became a research-oriented medical school. David Hamburg came from the NIMH in 1961 to chair the department, and he recruited a number of future leaders, such as William Dement, who founded sleep medicine as a clinical discipline as well as a research program; Jack Barchas, remembered for early work on the enkephalins and endorphins; and Helena Kraemer, who developed statistical research methods.

The department went on to become one of the main forces in U.S. psychiatry. Alan Schatzberg, a leader in psychopharmacology and coauthor with Charles Nemeroff of Textbook of Psychopharmacology (1998), came from McLean Hospital to serve as chair from 1991 to 2010. His own work centered on the adverse effects of hypercortisolemia and the development of glucocorticoid antagonists as treatments for psychosis. Laura Roberts, a leader in academic psychiatry and bioethics, was recruited from the Medical College of Wisconsin to serve as chair beginning in 2010.

LANGLEY PORTER CLINIC SAN FRANCISCO. In San Francisco, the Langley Porter Clinic, named after Dean Robert Langley Porter, who conceived it in the late 1930s, opened its doors in 1942 as a 100-bed

Telegram: @medical_k

www.konkur.in

psychiatric hospital. It later changed its name to the “Langley Porter Neuropsychiatric Institute” and then again to “Langley Porter Psychiatric Institute.” Writes historian Jurgen Ruesch in 1978, “It was based upon the idea that prevention, teaching, and research … would be enhanced if the wealth of clinical experience gained from the approximately 29,000 patients then available in the nine California state hospitals could be combined with the expertise of the staff of a medical school.” The inaugural director was Carl M. Bowman, who simultaneously became the first chair of the new division of psychiatry in the School of Medicine. Bowman was among the charter members in 1946, of the Society of Biological Psychiatry. In 1973, the hospital was transferred from the jurisdiction of the state to the University of California (as was the NPI in Los Angeles [see below]).

NEUROPSYCHIATRIC INSTITUTE LOS ANGELES. The UCLA was opened only in 1947, and Stafford Warren, the inaugural Dean, was said to have “dreamed of creating a ‘Langley Porter of the South.’” Norman Brill was brought from Georgetown in 1953 to become the founding chair of the Psychiatry Department, and in 1961, the first patients were admitted to the new NPI funded by the state government of California. A nearby Brain Research Institute also opened in 1961. Louis J. (“Jolly”) West came from the University of Oklahoma to chair the young psychiatry department, and West built staff from all around the world. In 1959, John French became the founding director of the Brain Research Institute. In 1973, the California State Department of Mental Hygiene transferred the NPI to the University of California, where it became part of the UCLA Health Sciences Center.

DIAGNOSIS

The two great arms of clinical psychiatry are diagnosis and treatment. The following sections are devoted to the histories of both.

Modern psychiatric diagnosis really begins with Philippe Pinel in Paris (see above), who in the second edition of his textbook in 1809

Telegram: @medical_k

www.konkur.in

enumerated four psychiatric diseases: (1) “mania, or general psychosis [délire]”; (2) “melancholia, or a specific delusion”; (3) “dementia, or abolition of thought”; (4) “idiotism, or the obliteration of the intellectual and affective faculties.” What he meant by these would parse into a number of distinct modern illnesses, but the point is that he did recognize several specific forms of previously undifferentiated “madness.”

After Pinel and Esquirol (see above), the most important figure in the history of nosology is Emil Kraepelin (“Krep-uh-leen”), professor of psychiatry in Heidelberg from 1891, in Munich from 1903, and author in 1883 of the influential psychiatric textbook, Psychiatry: a Textbook for Students and Physicians (*Psychiatrie: ein Lehrbuch für Studierende und Aerzte*), which reached international influence with its fourth edition in 1893 and became worldwide the dominant voice in psychiatry by the eighth edition, completed in 1915. Kraepelin had little patience with psychiatric theory or with pathologic anatomy and placed the diagnostic interest in psychiatry squarely on the clinical side, meaning at the bedside, especially on the course and outcome of the patient’s illness.

Kraepelin was the clinician’s clinician. On the basis of clinical course, Kraepelin said in 1899 that the two specific diseases in psychiatry were “manic-depressive insanity,” a mood disorder, and “dementia praecox,” or the dementia of adolescence, a thought disorder later called “schizophrenia.” He erected a firewall between them, one that still exists today, as in the DSM system, the cardinal disorders are “major depression,” as opposed to “schizophrenia.” No other historical figure in psychiatry, including Freud, has had the influence of Kraepelin upon contemporary psychiatry, although under the influence of psychoanalysis, U.S. interest in diagnosis did wane for several decades. Henri Ellenberger, a Swiss psychiatrist transplanted to Montreal, recalled in 1955, “I remember the consternation of a German psychiatrist hearing that certain American colleagues consider manic-depressive psychosis as a form of schizophrenia; for him, this was about as fantastic as the assumption that a camel is a subspecies of the elephant.”

Telegram: @medical_k

www.konkur.in

A page was turned with the advent of a distinctively American system of classification in 1945, the *Nomenclature of Psychiatric Disorders and Reactions*, which appeared as *War Department Technical Bulletin, Medical 203.* Spearheaded by psychoanalyst William Menninger, the head of consultation psychiatry in the U.S. Army during the war, “Medical 203” made wide use of psychoanalytic insights and underpinned the first effort of the American Psychiatric Association to classify illness, the *Diagnostic and Statistical Manual,* or “DSM-I” (the so-called subsequently) in 1952. (The APA itself was founded in 1844 as The Association of Medical Superintendents of American Institutions for the Insane, becoming the American Medico-Psychological Association in 1894 and the American Psychiatric Association in 1921.)

An even more psychoanalytically oriented volume, DSM-II, emerged in 1968.

In the 1970s, the APA drew up a new task force to make what were intended to be minor changes in DSM to bring it into accordance with the *International Classification of Diseases* (ICD) of the World Health Organization, appointing Robert Spitzer at the New York State Psychiatric Institute to lead it. Spitzer, however, disliked psychoanalysis and wanted a complete revision of the nosology to remove Freudian influences. In 1980 the revolutionary DSM-III emerged, which created such diagnoses as “major depression” and “attention deficit disorder” and anchored “bipolar disorder” firmly in the American classification. The subsequent editions of DSM—DSM-III-R in 1987, DSM-IV in 1994, and DSM-5 in 2013—changed little of this architecture, though in launching “bipolar two disorder” in 1994, DSM-IV did touch off an epidemic of “bipolar” in the pediatric population.

A rival system was the ICD of the World Health Organization. In 1938, an “international revision” conference of the League of Nations decided to add morbidity to its long-standing classification of mortality, and in 1948 the newly founded World Health Organization issued the “sixth revision” of the international lists (ICD-6). It contained such diagnoses as “delusional” insanity (other major

Telegram: @medical_k

www.konkur.in

psychiatric illnesses were cataloged under “dementia”). A distinct section on “mental disorders” was added in the ninth edition in 1975.

Over the years, the number of diagnoses in psychiatry has skyrocketed from four in Pinel to some three hundred in DSM-5. Some of these diagnoses may not stand the test of time. Yet, on a historical basis, several diagnoses do stand out as enduring and doubtless represent phenotypes of genuine underlying psychiatric diseases.

Specific Diagnoses

Melancholia. Melancholia, as distinct from generic “depression,” is one of the oldest diagnoses in medicine and goes back to the Ancients. Before the 19th century, melancholia tended to be an umbrella term for several varieties of psychosis and mood disorders that today would be recognized as distinct. Yet, at its core, melancholia has always stood for severe depressive mood disorder involving deep sadness, pervasive anhedonia, and psychomotor change, usually in the direction of slowing, but there is an anxious form of melancholia involving psychomotor acceleration as well. Timothie Bright, a Cambridge physician, in his 1586 book *A Treatise of Melancholie* described,

> the sorrowful humor which breeds in them … Of pace, they are for the most part slow … both by their members not so nimble for motion, and the mind occupied with cogitation stays [slows] the pace … Moreover, they are given to weeping sometimes … sighing, sobbing, lamentation, countenance demisse [downcast] and lowering.” Bright left a poignant image of weeping in melancholia, “It blears the eyes and makes the cheeks red; it causes the head to ache, the nose to run, and the mouth to flauer [labor], the lips to tremble; it interrupts the speech and shakes the whole chest with sighs and sobs.

In the 19th century, melancholia became differentiated from other kinds of depressive illness. Among the first to make this distinction was Richard von Krafft-Ebing in 1867, at the time a staff psychiatrist at the Illenau asylum (later, professor of psychiatry in Vienna). Krafft-Ebing distinguished between “simple depression of mood” (*die einfache Gemüthsdepression*) and severe depressions with anxiety

Telegram: @medical_k

www.konkur.in

and psychosis, including melancholia. The definitive distinction between “melancholia” and “depression” was ventured by Copenhagen psychiatrist Carl Georg Lange in his book on “periodic depressions” in 1886 (translated into German in 1892), which described these milder cases as distinct from (psychotic) melancholia.

The term “melancholia” went out of style around 1900 as Emil Kraepelin substituted “depression” for it, and Sigmund Freud decided that the depressive disorders did not qualify as the main psychoneuroses that psychoanalysis should be addressing. (But see above on a United States interested in “depressive neurosis.”) In recent decades, there has been a revival of interest in melancholia, as the field has begun to differentiate the heterogeneous basin of “major depression” on the basis of treatment response.

Psychotic Depression. In classical psychiatry, much melancholia was psychotic, and little was made of the distinction between psychotic and nonpsychotic. The difference later seemed unimportant because both groups responded equally well to ECT, introduced in 1938. Yet with the growing stigmatization of ECT after the 1960s, depression became treatable primarily with drugs, and in 1975, Alexander (Sandy) Glassman at the New York State Psychiatric Institute discovered that psychotic depression responded poorly to the standard tricyclic antidepressants (TCAs). Four years later, David Avery and Aldo Lubrano at the Palo Alto Veterans Hospital reported that psychotically depressed patients responded better to ECT than did nonpsychotically depressed. Under the leadership of Max Fink at the Stony Brook Campus of the State University of New York, ECT became defined as the most effective treatment of psychotic depression. Despite this evidence of differential responsiveness, psychotic depression continued to be downgraded as a mere “specifier” in the DSM.

Mania. Mania has undergone several transformations. For Pinel and the generations before him, it meant agitated dementia (“raving madness”). With François Fodéré in Strasbourg (1817), unbridled

Telegram: @medical_k

www.konkur.in

unreasoning outbursts became “furious mania.” In 1858, London psychiatrist Daniel Hack Tuke steered mania in the direction of an affective disorder rather than a disorder of intellect. “Although mania, in many instances, is prolonged anger, it may, likewise, be altogether pleasurable in its manifestations, presenting a condition of exhilaration and uncontrollable excitement, which is rather an excess of joy than of anger.” Then in 1881, Emanuel Ernst Mendel, senior lecturer in Berlin, anchored the term “hypomania” in the nosology, meaning elated mood, pressured speech, and increased motor activity. Mania entered DSM intact in 1952, and hypomania became official in 1994 in DSM-IV as “Bipolar II Disorder.”

Catatonia. Although individual symptoms of catatonia, such as waxy flexibility, had been described for centuries, catatonia as a clinical syndrome was recognized by Karl Kahlbaum only in 1874. Its independent existence was short, as in 1899, in the sixth edition of his Textbook, Kraepelin made it a “subtype” of schizophrenia, and for the next century, catatonia languished as an independent entity because, often when clinicians encountered it, they realized they were not dealing with schizophrenia and called it something else, or ignored it. In 1930, William Bleckwenn at the University of Wisconsin reported that catatonia responded to barbiturates, though this discovery was not widely appreciated. Karl Heinz Stauder, at the Munich University Psychiatric Hospital, described in 1934 a fatal version of catatonia, associated with hyperpyrexia.

The return of catatonia as an independent diagnosis separate from schizophrenia began in the 1970s. In 1976, Richard Abrams and Michael Alan Taylor at New York Medical College identified 20% of a sample of patients admitted to the psychiatric unit of a New York City hospital as having one more catatonia signs. Only 4 of the 55 satisfied the criteria for schizophrenia, while more than two-thirds had affective disorders, usually mania. In the context of growing interest in catatonia as independent of schizophrenia, in 1983, Gregory Fricchione at Stony Brook recommended benzodiazepines, especially lorazepam, in the treatment of catatonia instead of barbiturates. Various syndromes previously seen as separate began

Telegram: @medical_k

www.konkur.in

to be recognized as catatonic in nature: In 1996, it was suggested that toxic serotonin syndrome (TSS) might be a form of catatonia. A symposium at the American Psychiatric Association meeting in 2000 concluded that neuroleptic malignant syndrome (NMS) and malignant catatonia were the same. In 2011, Dirk Dhossche at the University of Mississippi and colleagues raised the possibility that anti-NMDA receptor encephalitis was a form of catatonia. The American Psychiatric Association responded to this series of new catatonia findings by making catatonia a virtually independent disease entity in the DSM-5 published in 2013.

Delusional Disorders

Delusional disorders, meaning fixed, systematic false beliefs, were recognized in 1816 with Etienne Esquirol's "monomania." He said that the psychosis (*délire*) is fixed on one object alone. As early as 1865, then definitively in 1874, Ludwig DC Snell, director of the asylum in Hildesheim, Germany, distinguished between primary and secondary delusions (*Wahn*), primary meaning fixed, false ideas not caused by another illness and not deteriorating; vague secondary delusions could lead to "the collapse of the entire psychic life," something Snell observed in the kind of illness later called "schizophrenia." This was the beginning of separating delusional disorders from chronic deteriorating psychosis as the former were false beliefs that were fixed, systematic, and did not affect other areas of intellectual functioning.

Anxiety. The term "anxiety" has long been used in psychiatry. In 1769, a young medical graduate of Leiden University ventured a dissertation on "Anxietate," and the term was clearly current among his professors. Yet, the German clinical tradition of the 19th century frowned on anxiety as an independent diagnosis. In Emil Kraepelin's big textbook, there is no freestanding "anxiety" disorder. But it was not just Kraepelinian obdurance. The "anxiety" entry in Daniel Hack Tuke's *Dictionary of Psychological Medicine* (1892) is only two sentences long. What placed anxiety in the center of psychiatry's

Telegram: @medical_k

www.konkur.in

radar was Freud's belief that anxiety was the basic motor of symptom formation: anxiety arose as a result of intrapsychic conflict over various drives. The entries for "anxiety" (*Angst*) in the general index of Freud's writings extended for eleven pages ("genitals," by contrast, only for four). Accordingly, anxiety has always assumed a disproportionate role in psychoanalytically oriented American psychiatry (mixed anxiety-depression has tended to loom more prominently for the British). DSM-I in 1952 prefaced its discussion of "psychoneurotic disorders" by claiming that, "The chief characteristic of these disorders is 'anxiety'…." and in the discussion that followed "anxiety" figured importantly in each, such as "dissociative reaction," "obsessive-compulsive reaction," and so forth. DSM-III in 1980, although antipsychoanalytic in inspiration, continued the centrality of anxiety while beginning its fragmentation into specific anxiety disorders, of which there were ten. Subsequent editions of DSM have continued this tradition.

Chronic Primary Psychosis (Schizophrenia). Psychiatry has struggled over the years with chronic deteriorating psychotic illness, leading either to some kind of deficit or to the dissolution of the personality (once called "dementia"). Developments in psychiatry's two major cradles are chronicled separately.

FRANCE. In 1852, Bénédict-Augustin Morel, then at the Maréville asylum in eastern France (but shortly to head the St-Yon asylum outside of Rouen) called such psychoses of adolescent-onset *démence précoce*, or premature dementia (see above). In 1857, he applied the notion of "degeneration," or worsening across the generations, to psychiatric illness (*Traité des Dégérérescences*) and 1860, in one of the most famous declarations in the history of psychiatry, in his *Treatise on Mental Illness* (*Traité des Maladies Mentales*) he avowed premature dementia in the young to be a consequence of degeneration.

In 1883, Valentin Magnan, a staff psychiatrist at the Sainte-Anne Clinical Asylum in Paris, described "chronic psychosis"—he later added the qualifier "involving systematic evolution"—an often-

Telegram: @medical_k

www.konkur.in

deteriorating form of psychosis in patients who were not hereditarily predisposed. This remained quite influential in France, though elsewhere, it was eclipsed by “schizophrenia” (see below).

French experimentation with chronic psychosis continued, even as Magnan’s degeneration-based doctrines were discredited, and in 1910, Maurice Dide, at a psychiatric hospital in Toulouse, proposed “chronic hallucinatory psychosis,” which, though severe, did not deteriorate. To this day, the concept has remained influential in France without reaching a larger international audience.

GERMANY. Meanwhile, in Germany, a different approach to chronic psychosis was being elaborated: deterioration to “dementia,” or at least to a severe deficit. In an 1863 book on the classification of psychiatric illness, Karl Kahlbaum, a staff psychiatrist at the East Prussian provincial asylum of Allenberg, differentiated a “deteriorating psychosis,” which he called *Vesania typica*, which ran its course in four stages, the last of which was “dementia.” Vesania was a customary term at the time for chronic psychosis. In 1871, Kahlbaum and his student Ewald Hecker differentiated further a version of this Vesania beginning in adolescence that they called *hebephrenia*. Hebephrenia, like Vesania typica, usually ended in dementia. (Although Hecker’s name appeared alone on the paper, it was understood that the concept was really Kahlbaum’s.)

At this point, a considerable amount of European scholarship, dating from Morel in 1852, had accumulated that linked chronic deteriorating psychosis to onset in adolescence. In 1893, Kraepelin synthesized this literature in a concept that was to sit rock-solid in psychiatry for more than a century: *dementia praecox*. Over the next decade, he identified three subforms of it: hebephrenic, catatonic, and paranoid. They had in common a begin usually in adolescence or young adulthood, and a downhill course to “dementia.” So magisterial was the Kraepelinian synthesis that all previous writing on chronic psychosis became virtually forgotten. In 1908, Eugen Bleuler, professor of psychiatry in Zurich, baptized Kraepelin’s dementia praecox as “schizophrenia,” seeing it as a much milder disease and not linked to adolescence. Bleuler’s schizophrenia

Telegram: @medical_k

www.konkur.in

remains little changed today, a single deteriorating psychotic disorder that may onset at any point in life and that may well end in "defect" (or social remission), even if "dementia" as the end stage of the illness has stopped being spoken of. In 2013, DSM-5 dispensed with the famous Kraepelinian "subtypes."

Many "schizophrenia" patients may spend long periods without being actively psychotic; the primary symptoms seem to be emotional blunting with avolition and a formal thought disorder.

Brief Reactive Psychosis or Brief Psychotic Disorder

Chronic psychotic illness had long been seen as something indwelling and constitutional. The alternative notion that psychosis could arise from stress was codified as *la bouffée délirante* by two students of Valentin Magnan at Sainte Anne in Paris in 1886, then by Magnan himself in 1891—who saw it as arising mainly in the "degenerate." August Wimmer at St. Hans Hospital in Denmark christened it "psychogenic psychosis" in 1916, with an emphasis on reaction rather than degeneration. Then in 1968, Eric Strömgren in Aarhus, Denmark, revived Wimmer's concept in an influential (in Scandinavia) paper on "reactive psychoses," a term that he changed in 1974 to "psychogenic psychoses." In 1980, DSM-III recognized "brief reactive psychosis," with no reference to any of these other international terms. (These developments are charted in Shorter, *Historical Dictionary*.) The French translation in 1989 of DSM-III-R makes no reference to bouffée délirante and mentions only *psychose reactionnelle brève*, an interesting example of the collapse of these once distinctive national nosologic traditions.

Bipolar Disorder

The "bipolar disorder" of DSM is not Kraepelin's "manic-depressive insanity," which Kraepelin insisted included all depressions of whatever polarity, mania, hypomania, and the attendant anxiety. Rather, in his 1948 textbook Karl Leonhard, then in Frankfurt am Main and a student of Karl Kleist (who introduced the concept of *phasic psychoses*, or illnesses that alternate from one state to

Telegram: @medical_k

www.konkur.in

another), proposed the term “bipolarity” for the alternation of depression and mania as an illness separate from unipolar depression. In 1957, *in The Classification of the Endogenous Psychoses* (*Die Einteilung der endogenen Psychosen*), Leonhard asserted that unipolar depression had a different psychopathology from the bipolar variety. Filled with neologisms and lacking in quantitation, the book had a limited international impact. Yet a small cadre of investigators, such as Frank Fish in England, Helmut Beckmann in Germany, and George Winokur in the United States, became enthusiasts of the Leonhardian notion of bipolar disorder and managed to insert it in the literature, so that by 1980 when DSM-III was published, bipolar disorder was self-understood as a different disease from unipolar depression (in DSM-III called major depression).

Trauma and Its Sequelae

Ever since Napoleon’s disastrous retreat from Moscow in 1812, psychiatry has recognized that symptoms may arise from great stress. (In Napoleon’s case, of an army of 400,000 that set out, 7,000 returned. Along the way, much “nostalgia” was witnessed—an early label for fatal catatonia.) In 1866, London surgeon John Eric Erichsen originated the diagnosis of “railway spine,” vague and nonspecific symptoms supposedly attributable to the “spine” in minor railway mishaps. Carol Moeli, a Berlin psychiatrist, elaborated in 1881 upon the specific psychiatric consequences of such events, penning the first description of what became known as post-traumatic stress disorder (PTSD). In 1881 as well, Berlin neurologist Hermann Oppenheim coined the phrase “traumatic neurosis,” psychiatric and neurologic symptoms arising from shock.

The First World War spawned a whole raft of descriptions of psychological sequelae from combat, of which terms the most lasting has been “shell shock”—from Charles S. Myers in 1915. The Second World War gave birth to “combat fatigue” as a synonym for war neurosis. Meanwhile, a tragic fire in 1942 at the Cocoanut Grove nightclub in Boston gave rise in 1944 to “acute grief” as yet another

Telegram: @medical_k

www.konkur.in

term for acute stress reaction. Most recently, following a sustained political campaign by the veterans of the Vietnam War—and spearheaded by Yale psychiatrist Rober Lifton—DSM-III in 1980 coined the term “posttraumatic stress disorder.” This diagnosis has been among the most rapidly proliferating in U.S. psychiatry.

Dementia

The dementias have always been a problem for psychiatry, as the field has struggled to differentiate loss of intellectual function from personality deterioration. In 1814, Etienne Esquirol took up the idea of his teacher Pinel of dementia as a distinct disease entity, separate from melancholy, mania, and imbecility. “There exists a very distinctive kind of insanity in which the disorder of ideas, sentiments, and determinations is characterized by the weakness and the more or less pronounced abolition of all the sensory, intellectual and moral faculties.” In particular, Esquirol differentiated senile dementia from other conditions of “weakmindedness.” (Shorter, *Historical Dictionary of Psychiatry*, chronicles developments in dementia.) There followed a long series of differentiations of the organic dementias: Sergei Korsakoff distinguished ethanol-related amnesia (Korsakoff psychosis) from dementia in 1887; Alois Alzheimer distinguished “presenile” dementia from the senile variety in 1906; in 1926, Hugo Spatz, head of neuropathology at the Munich University Psychiatric Clinic, suggested that a distinctive frontal- and temporal-lobe wasting should be called “Pick’s Disease” after Arnold Pick, professor of psychiatry at the German university in Prague, who first reported it in 1892; in 1912, Friedrich Heinrich Lewy described distinctive intracytoplasmic inclusions, later called “Lewy bodies,” which he detected in the brain stem in Parkinsonism; and in 1962, neuropathologist John S. Woodard at the Camarillo State Hospital in California, proposed Lewy-body dementia as a separate form of dementia; in 1948, London psychiatrist Robert Denis Newton codified long-established German thinking that presenile Alzheimer’s and the dementia of senescence represented a single pathologic process, and suggested calling it “Alzheimer’s dementia”; Raymond

Telegram: @medical_k

www.konkur.in

Adams at Harvard University and Maurice Victor at Case Western University, emphasized in 1977, that Alzheimer disease was not just an accelerated extension of old age but a pathologic eruption into it.

Ever since New Jersey pathologist Harrison Stanford Martland's paper "Punch Drunk" in 1928, repeated cranial trauma has been considered a distinct cause of dementia. Martland said, "Fighters in whom the early symptoms are well recognized are said by the fans to be 'cuckoo,' 'goofy,' 'cutting paper dolls,' or 'slug nutty.'" Since then, physicians have been alerted to the neuropsychiatric consequences of repeated head trauma. In 1937, in the U.S. Naval Medical Bulletin, naval surgeon J.A. Millspaugh called it *Dementia Pugilistica*. In a paper in the British Medical Journal in 1989, on "Boxing and the brain," John Arthur Nicholas Corsellis pulled this literature together in a red warning light about repeated head trauma. By the new millennium, these concerns about early dementia had been expanded to all sports involving repeated head trauma.

Neurosis

The classic distinction between psychosis and neurosis was abolished in DSM-III in 1980. Neurosis, as a term, is among the oldest in psychiatry; it was introduced by Edinburgh physician and nosologist William Cullen in his *First Lines in the Practice of Physic* in 1777 to mean diseases of the nervous system without an obvious physical lesion. In the next half-century, it came to be synonymous with brain disorder. It was Richard von Krafft-Ebing, in his *Textbook of Psychiatry* (*Lehrbuch der Psychiatrie*) in 1872, who coined the term "psychoneurosis," meaning mental illnesses that affect normal brains (in contrast to brains affected with "degeneration"). Sigmund Freud used the term psychoneurosis for the first time in his writing in 1898. But neurosis had by that time long entered medicine, and Freud proceeded to employ it as a synonym for "disorder." After Freud, neurosis remained largely in the area of psychoanalytic discourse, which was the dominant discourse in psychiatry until DSM-III in 1980.

NEW TECHNIQUES

Psychiatry is not among the most technologic of medical specialties. Yet changes in technique have expanded the range of its knowledge and enhanced the diagnostic and therapeutic abilities of its practitioners.

Epidemiology

The study of epidemiology had an early bump-up with the observation of Thomas Clouston in 1873, in the *Journal of Mental Science* that,

> The wide series of diseases which are at present called insanity prevail more in some places than in others … When one comes to look carefully into the reports of lunatic asylums in different parts of the country it is found that there are forms of brain disease (or varieties of insanity as they are called) present in abundance in one place which have almost no existence in another … This investigation must be very largely conducted on the numerical method. (Clouston TS. The local distribution of insanity and its varieties in England and Wales. *J Ment Sci.* 1873;19(85):1–19, reproduced with permission.)

Yet, it was the Germans who initially picked up this torch. At the German Psychiatric Research Institute (*Deutsche Forschungsanstalt*) in Munich, founded in 1917, by Emil Kraepelin, Swiss psychiatrist and geneticist Ernst Rüdin, inaugural director of the eugenics research institute of the DFA, led studies on psychiatric epidemiology (cross-sectional) and genetics (longitudinal). Unfortunately, in the Third Reich, Rüdin had a particularly unsavory involvement with public policy, arguing for the Nazi racial and sterilization laws, and after 1945 was briefly interned in the United States. This National Socialist involvement of the DFA and other German groups lent to psychiatric epidemiology and genetics a bad odor that retarded the development of the field for decades.

It was in Denmark that Eric Strömgren, the most important psychiatric epidemiologist of the pre-1970 period, flourished. As a student, he visited the Rüdin group in 1935; he undertook in 1938 what became an epidemiologic classic of the small island of Bornholm. He became a professor of psychiatry in 1945 and was

Telegram: @medical_k

www.konkur.in

instrumental in organizing the Danish Psychiatric Central Registry at Aarhus, which in 1969 became an electronic register of everyone in Denmark admitted to a psychiatric service. By 2011, this famous register contained over 700,000 individuals and more than 3 million treatment episodes. One offshoot of this was the Danish-American cohort study in 1968, led by David Rosenthal, Paul Wender, and Seymour Kety at NIMH. It merged two registers: that of children who had been adopted away and that of admissions to psychiatric hospitals. This remarkable database permitted the NIMH collaborators, together with Fini Schulsinger in Copenhagen and other Danish colleagues, to determine that children adopted from schizophrenia families but raised in normal homes often became schizophrenic. It was a major blow to the "nurture" school. At a conference in Dorado, Puerto Rico, where these results were first presented, Rosenthal said, "The case for heredity has held up convincingly. At the moment, I can see no grounds for withholding affirmation any longer."

In the United States, the National Institute of Mental Health sponsored, in the 1980s, the 5-site Epidemiological Catchment Area (ECA) study, the first to inquire about diseases rather than symptoms, the results of which were reported in 1991. Myrna Weisman at Columbia later said in an interview the big finding of the ECA was that "These disorders begin in the young … often in adolescence, and certainly, by young adulthood … So, the biggest contribution of the ECA was turning the focus on young people and their high rates of psychiatric disorders."

In the early 1990s, NIMH sponsored the National Comorbidity Survey (NCS) to assess the prevalence of DSM-III-R disorders in a nationally representative sample. Early in the new century, the NCS was redone in the National Comorbidity Survey Replication (NCS-R), using the international WHO Composite International Diagnostic Interview to collect DSM-IV diagnoses from a household survey and to make international comparisons possible.

Statistics

Telegram: @medical_k

www.konkur.in

Paris psychiatrist Jean-Pierre Falret's critique of the counting method in 1864, in the preface of his On Mental Illness (*Des maladies mentales*), has not lost its relevance today: "Statistics as a procedure are in fact all the more dangerous because they offer all the appearance of truth." Falret scorned the statistics of the day as failing to include homogeneous clinical populations and using abstractions overly divorced from reality. Modern statistical theory, as Bernard Carroll traces events, originated in the last quarter of the 19th century and the first quarter of the 20th century. Regression to the mean was described in 1877; regression and correlation analysis in 1888 by Francis Galton; the Chi-squared test in 1900 was originated by Karl Pearson; the student's t-test in 1908 by W.S. Gossett; the analysis of variance (ANOVA) comes from RA Fisher in 1919; power analysis, confidence intervals, Type I and Type II error originated in the 1930s from Jerzy Neyman and Egon Pearson. But these advances were not incorporated as research tools into the clinical science of psychiatry until well beyond the 1930s.

The early use of statistics in psychiatry consisted essentially in tabular bookkeeping—simple descriptive statistics such as census details, cohort descriptions by age, age of onset, sex, or outcome. Use of statistics to test hypotheses in psychiatry came much later. Emil Kraepelin maintained detailed counting cards (Zählkarten) of cases he observed, leading up to his landmark distinction between dementia praecox and manic depressive insanity (see above). Assen Jablensky's 1993 reanalysis of those cases with modern statistical methods essentially confirmed the existence of two separate disorders that Kraepelin had recognized by informal Gestalt inferential methods. The same cannot be said of Aubrey Lewis, whose 1934 discussion of depressive illness confidently announced a single-dimensional model without the benefit of any statistical analyses. That position became dogma within Maudsley Hospital circles and led to conflict with the Newcastle school under Martin Roth. Eventually, Lewis's primary data were subjected in 1977 to modern statistical analysis by Lesley Kiloh and Roger Garside (two of the original Newcastle group), and they were found actually to support the Newcastle binary model. These two examples illustrate

Telegram: @medical_k

www.konkur.in

the absence of reliable means to validate the proposals of clinical experts before the entry of statistics into psychiatric research.

Aside from elementary analytic procedures such as group comparisons (in categorical and dimensional versions), significance testing, and correlations (all in parametric and nonparametric versions), the major statistical themes that moved psychiatric research were numerical taxonomy and psychometrics. Derived from advances in basic statistics, these approaches appeared first within academic psychology for the study of personality traits and dimensions of psychopathology. For the most part, they were slow to be taken up within the discipline of psychiatry and, when they were, the history of their adoption is inseparable from the history of clinical assessment instruments that relied on the new statistical approaches. In parallel, innovations in basic statistical theory and technique also were adopted within psychiatry for clinical trials, as well as for epidemiologic and genetic studies.

Factor Analysis and Personality Inventories

Factor analysis originated with Charles Spearman and Raymond Cattell. The psychological sciences adopted the technique in the 1930s. In parallel, the Minnesota Multiphasic Personality Inventory (MMPI) was under development by Starke R. Hathaway and J. Charnley McKinley at the University of Minnesota from the late 1930s. Local use apparently began in 1939. The original published version appeared in *JAMA* in 1943: The MMPI has seen many later revisions. A perceived advantage was casting it as a descriptive and atheoretical approach to personality and psychopathology, not derived from psychoanalytic theory. Over the years, cultural and ethnic biases in the MMPI have been alleged. Nevertheless, it attained widespread use in education, clinical psychology, and employment screening. A scoring innovation for the MMPI was the devising of T-scores—a standardized metric where the mean is set at 50 and the SD at 10. Other scales adopted the same scoring approach, which had the benefit of standardizing responses and allowing cross-scale comparisons. In parallel, Raymond B. Cattell

Telegram: @medical_k

www.konkur.in

devised in 1946 a personality inventory for which factor analysis was an essential component. His psychometric instrument is famous as the Cattell 16PF personality factors inventory.

Controlled Trials

The first controlled trial in psychiatry was reported in 1922 in the *American Journal of Psychiatry* by Clarence O. Cheney, assistant director of the New York State Psychiatric Institute, then at Ward's Island, and bacteriologist Nicholas Kopeloff. They wanted to establish whether the organ removals (colectomies, teeth, etc.) then in vogue for the treatment of mental illness were, in fact, effective, and to do so, they studied 60 patients with "focal infections" among the general admissions to the Manhattan State Hospital on Ward's Island, dividing them into two groups, the "operated group" receiving operative treatment for their " 'foci' of infection" versus those not so treated (the "control group"). They found, "On the whole, the operated group appears to have received no more benefit than the control group."

Following the tuberculosis studies of Bradford Hill after the Second World War, randomizing the patients to control or treatment groups became increasingly common. The first randomized controlled trial in psychiatry with "blinded" investigators was conducted in 1955 by David Lewis Davies and Michael Shepherd at the Maudsley Hospital, comparing reserpine to placebo in the treatment of "anxious and depressed patients."

The use of probabilistic statistics in psychiatry has a much more recent origin. Four statistics are used to measure the reduction of risk in treatment (two of them compare vs. lack of treatment). (The following discussion cribs from Andreas Laupacis and collaborators, 1988.)

- **The relative risk reduction (i.e., how much risk reduction in percent).** This is the classic measure.
- **The "odds ratio."** A probability (P) of 0.25 (one chance in four) represents odds of 1:3 or 1/3. This is insensitive to a difference in

Telegram: @medical_k

www.konkur.in

risk in the absence of therapy. It was introduced by N. Mantel and W. Haenszel in 1959.

- **Absolute risk reduction.** The differences in event rates between the control and treatment groups. A genuine measure of absolute risk reduction but expressed as a decimal, “This measure may be difficult for [physicians] to remember and incorporate into clinical practice,” say Laupacis and colleagues.
- **Number needed to be treated (NTT).** The number of patients who must be treated in order to prevent one adverse event. Laupacis and colleagues proposed this in 1988. “It tells clinicians and patients in more concrete terms how much effort they must expend to prevent one event, thus allowing comparisons …” Although many clinicians will be put off by such exercises, these statistics mark the definitive passage from psychoanalysis with its evidentiary base of anecdotes to modern clinical psychiatry that employs the same evidentiary base as the rest of medicine.

Tests in Psychiatry

Despite protestations that psychiatry “has no diagnostic tests,” there are, in fact, quite a few. In 1906, August Wassermann and colleagues at the University of Berlin described a diagnostic test for “progressive paralysis” (what neurosyphilis was then called) based on the patient’s blood or cerebrospinal fluid. In 1913, Hideo Noguchi, a microbiologist at the Rockefeller Institute for Medical Research, succeeded in obtaining a culture of *Treponema pallidum* in a sample of the brains of neurosyphilitic patients who carried the diagnosis of “general paralysis of the insane,” the English equivalent of “progressive paralysis.” Therewith, neurosyphilis became identified as an infectious disease and passed from the purview of psychiatry, where it had lodged for the previous century. In 1931, Hans Berger in Jena used the EEG, which he had just invented, to confirm a specific pattern of brain waves in a patient with epilepsy. These were early diagnostic tests in psychiatry.

More were to come. A group of researchers led by Charles Bradley at the Emma Pendleton Bradley Home in East Providence, Rhode Island, established in 1938 that a certain subset of children

Telegram: @medical_k

www.konkur.in

who would later be called “hyperactive” (with the diagnosis of attention-deficit/hyperactivity disorder, ADHD) demonstrated a specific electroencephalographic pattern. The test remains controversial, but it has not been disallowed. In 1940, Mandel Cohen and Stanley Cobb, psychiatrists at Harvard, reported in The Journal of Clinical Investigation that carbon dioxide could precipitate what were later called “panic attacks” in patients prone to anxiety. Abnormalities in serum lactate thus became a biologic marker for panic, and there followed a considerable history of using “panicogens” to study panic.

As early as 1958, “pharmaco-EEG” was used to “classify psychopharmacologic drugs and predict their clinical applications,” as Max Fink, a pioneer of the technique, later put it. Then in 1962, in a study published in the American Journal of Psychiatry, Fink and Donald Klein, part of the Hillside Hospital Experimental Team, established in a proper randomized controlled trial of chlorpromazine and imipramine that depressed patients responded well to imipramine, schizophrenics did not. The imipramine challenge was the first biologic test for serious depression.

Bernard Carroll at the Royal Melbourne Hospital applied the DST in 1968 to confirm the presence of melancholic depression. The DST, based on a dexamethasone challenge to the hypothalamic–pituitary–adrenal (HPA) axis, establishes HPA dysregulation in patients with severe mood disorders. In 1983, Gregory Fricchione and colleagues at Harvard reported that catatonia is responsive to the benzodiazepine lorazepam. In their 2003 book on catatonia, Max Fink and Michael Alan Taylor proposed a one- or two-dose benzodiazepine challenge as a convincing diagnostic test for catatonia. Biologic psychiatry proceeds from the premise that behavioral disorders are symptoms of underlying cerebral dysfunction. It is therefore unsurprising that biochemical markers have long existed in psychiatry.

Convulsive and Coma Therapy

Telegram: @medical_k

www.konkur.in

Convulsive therapy, probably the most powerful psychiatric treatment on offer, had its origins in the 1930s, together with the other so-called “physical therapies” that addressed the brain itself.

First of the new physical treatments was insulin coma therapy, introduced in 1930 with the discovery by Manfred Sakel, then an assistant physician in a private nervous clinic in Berlin, that the withdrawal symptoms from morphine addiction could be relieved with insulin. It soon became apparent that the curative agent was an insulin-induced coma, and when, after the Nazi seizure of power in 1933, Sakel returned to his native Vienna, he persuaded the professor of psychiatry, Otto Pötzl, to let him experiment with insulin coma in the treatment of schizophrenia. From this work issued in 1934, a series of articles in a Viennese medical weekly that turned into a book in 1935, *A New Method of Treating Schizophrenia* (*Eine neue Behandlungsmethode der Schizophrenie*). A series of insulin comas does seem to have had a certain effectiveness in relieving the symptoms of chronic psychosis, and insulin remains today an underexplored agent in psychiatry. Some of Sakel’s patients also experienced seizures, and these as well may have been a therapeutic mechanism.

It was Budapest psychiatrist Ladislaus von Meduna who, in 1935, began the systematic exploration of chemically induced cerebral convulsions as a treatment. Meduna initially used camphor to initiate brain seizures, then the heart drug pentylenetetrazol. Meduna experienced extraordinary successes, especially in patients with the symptoms of catatonia, and his 1935 report in the Journal of Combined Psychiatry and Neurology (*Zeitschrift für die gesamte Neurologie und Psychiatrie*) is of historic importance in introducing the concept of therapeutic seizures to psychiatry. Yet many patients resisted chemically induced seizures because of the anxiety they experienced in waiting for the seizure to begin.

In 1938, Rome psychiatry professor Ugo Cerletti hit upon the idea of inducing the seizures with electricity so that the patients were instantly unconscious and underwent no anxious latency period. He quickly discovered that patients with melancholic depression responded readily to ECT, and the technique spread rapidly

Telegram: @medical_k

www.konkur.in

throughout psychiatry; it was at the time relatively uncontroversial. Cerletti had demonstrated not that convulsive therapy was effective (Meduna's doing) but, as modern ECT-investigator Richard Abrams puts it in his 1988 manual of convulsive therapy, "that such convulsions could be induced safely, reliably, and inexpensively by electrical means." Cerletti and the other early electrotherapists did not restrain their patients, and as a result, the "unmodified" seizures resulted in numerous fractures. To reduce such side effects, curare was first employed as a means of blocking the nerve–muscle junction, then, in 1952, succinylcholine, together with a barbiturate anesthetic. Yet even this modified ECT became in the 1960s an object of opprobrium in the counter-culture and then in the eyes of the pharmaceutical industry, which insisted that psychopharmacology could replace convulsive therapy. But it turned out that ECT offered distinct advantages in the treatment of melancholic depression, mania, and catatonia, and in 1978 the American Psychiatry Association offered an endorsement of it to counter the ballooning stigma caused in particular by the 1975 Hollywood movie, *One Flew Over the Cuckoo's Nest*. Max Fink, at the Stony Brook School of Medicine, led a campaign to rescue ECT from threatened oblivion. In 1990, the APA issued a much more enthusiastic endorsement of ECT, and it would be fair to say (as David Healy and I do in our 2007 history of shock therapy) that ECT has now resumed its prominent place in the panoply of psychiatric treatments.

Neuroimaging

Neuroimaging dates back to Harvey Cushing's 1896 radiograph of the cervical spine of a patient who had just been shot in the neck; the history of neuroimaging includes air encephalography, introduced in 1918 and used in Germany in 1927, to identify enlargements of the ventricular system in patients with schizophrenia. Gerd Huber's classic 1957 monograph *Pneumoencephalography and Psychopathology in the Endogenous Psychoses* (*Pneumooencephalographische und psychopathologische Bilder bei*

Telegram: @medical_k

www.konkur.in

endogenen Psychosen) was probably the high water mark of pneumoencephalography in psychiatry.

Carotid angiography, introduced in 1927, has never had significant psychiatric uses. But radionuclide brain scanning commenced in 1948, showed great promise once radioactive ligands were introduced in the 1970s in the form of single-photon emission tomography (SPECT) and positron emission tomography (PET).

Tom Bolwig, professor of psychiatry at the University of Copenhagen, outlines the following story: Among the earliest studies, in 1974 David H. Ingvar and Göran Franzen at Lund University reported in the Acta Psychiatrica Scandinavica decreased cerebral blood flow in chronic schizophrenia. SPECT and PET were employed in the 1980s to measure regional cerebral blood flow and metabolism and, later, neurotransmitter-binding potential. SPECT and PET are used as well to quantify the regional density of receptors of a given type and receptor-binding displacement. But these methods expose patients to radioligands and demand cyclotron capacity, so they cannot be applied outside of specialized centers. In 1988, Daniel Weinberger and associates at the NIMH employed PET to help develop the “hypofrontality” hypothesis in schizophrenia.

Magnetic Resonance Imaging

Magnetic resonance imaging (MRI) entered medicine in the late 1970s. In psychiatry, the first controlled study using MRI was led by Nancy Andreasen, finding in 1986 in the Archives of General Psychiatry that a population of schizophrenic males had “markedly smaller frontal lobes.” Functional MRI (fMRI) examines changes in blood oxygen level, a proxy measure of neural activity. The Yvette Sheline group at Washington University in St. Louis used fMRI in 2002 to demonstrate that long-standing depression produced a decrease in 5-HT(2A) receptors in the hippocampus, a functional finding. Structural MRI measures brain and regional gray and white matter volumes and was used in 2003 by Sheline and colleagues to measure the loss of hippocampal volume in severe untreated

Telegram: @medical_k

www.konkur.in

depression (the longer untreated, the greater the loss of volume). Thus, in Sheline's terms (in the 2002 article), "Functional imaging extends the sensitivity and specificity of structural imaging."

Brain Connectivity

Brain connectivity refers to a pattern of anatomical links ("anatomical connectivity"), statistical dependencies ("functional connectivity"), or causal interactions ("effective connectivity") between distinct units within the nervous system. Using a variety of MRI and fMRI methodologies, information about the functional and structural integrity of neural circuitry—"neural profiles"—can be provided in healthy and psychiatrically unwell individuals. In 2008, M.L. Phillips and associates identified abnormalities of connectivity in the neural circuitry supporting emotion processing and regulation in bipolar disorder. In 2010, in Biologic Psychiatry, Amelia Versace and colleagues attempted to differentiate unipolar versus bipolar depression on the basis of the functional white matter integrity of the neural circuitry regulating emotion.

Quantitative EEG (QEEG) Brain Mapping

Introduced in the 1980s, the QEEG brain map produces a three-dimensional reconstruction of the brain's activity. Using advanced algorithms, it is possible to identify brain-wave patterns from deep brain structures. The method is noninvasive but has a space resolution weaker than that of the above-mentioned methods. QEEG has been used by ER John and associates to identify activity clusters in a variety of different psychotic states. One reason for the lesser popularity of QEEG compared to SPECT, PET, and MRI may be, as Tom Bolwig observes, "that understanding the elements of electrophysiology seems a bit harder for many physicians than accepting colored spots on an image of the brain." Yet QEEG represents pure neuronal transport and can record immediately and for very long periods of time, which are essential qualities for monitoring chains of events.

www.konkur.in

THE BEGINNING OF THE SECOND BIOLOGIC PSYCHIATRY

Psychiatry in Europe, with its heavy emphasis on heredity, had always been biologically oriented. But in the 1930s, psychoanalysis in the United States wiped the biologic slate clean. Then in 1946, at a meeting at the Fairmont Hotel in San Francisco, the biologic thread began to re-emerge. Two California physicians—Johannes M. Nielsen, a neurologist at the University of Southern California, and his student, George N. Thompson, chief psychiatrist at the Los Angeles General Hospital, convoked those interested in "the biological basis of behavior." The meeting was attended by the heavyweights in U.S. neurology and psychiatry: Percival Bailey, a Chicago neurologist; Stanley Cobb, professor of neuropathology at Harvard; and Karl M. Bowman, at the Langley Porter clinic in San Francisco. From this meeting emerged the Society of Biological Psychiatry. In 1947, Nielsen and Thompson published the first textbook of biologic psychiatry in the United States, *The Engrammes of Psychiatry*.

The Revolution in Psychopharmacology

Although the term "psychopharmacology" seems to have been coined by David Macht, a pharmacologist at Johns Hopkins University, in 1920, to describe "the effect of drugs on psychological functions," it was not until the mid-1950s, with the explosion of interest in mechanisms prompted by the success of the antipsychotics, that the term started to come into use. When Paris psychiatrist Jean Thuillier visited Joel Elkes's newly founded department of experimental psychiatry in Birmingham in the mid-1950s, he was introduced by Willy Meyer-Gross. (Meyer-Gross, a refugee from Hitlerism who previously had been a mainstay at Heidelberg, was finishing his career in Birmingham as an associate of Elkes.) Meyer-Gross said in the introduction, "From everything that will be said to you this evening, bear in mind this new word: psychopharmacology. We already practise it here without realizing it,

Telegram: @medical_k

www.konkur.in

and everything we do tomorrow and in the future, everything we will want to do, will be gathered into this new discipline."

There has been much discussion pro and con about psychiatry's turn toward psychopharmacology. For all current concerns about polypharmacy and "cosmetic psychopharmacology," one does well to bear in mind the recollections of Robert Felix, inaugural director of NIMH in 1949, of his days as a resident in a mental hospital in 1931,

> He explained that continuous flow baths were generally used for disturbed patients. "If the patient was too disturbed to lie in the tub, either a hot or a cold pack was used," which, while not specifically identified as such, acted as an effective physical restraint. For agitated patients, whether excited or depressed, "three chemical substances were used: paraldehyde, phenobarbital, or bromide." Felix noted that their bible was chapter XI of Bleuler's Textbook of Psychiatry. 'The Treatment of Mental Diseases in General'

In the years after the Second World War, psychiatry swung on a massive hinge. "There can be no twisted thought without a twisted molecule," wrote Ralph Gerard in 1955 in the American Journal of Psychiatry, keynoting the advent of a new era in psychiatry, the easing away from psychoanalysis, and the turn to pharmacotherapeutics as the main treatment modality. Biology marked, said Gerard 2 years later in Science, "the emphatic re-entry of the brain into the mental arena." In these years, the field evolved from being the lowest prescribing of the medical specialties to the highest. (In 2005, 90.1% of all psychiatric visits ended with a prescription; the next highest was cardiovascular diseases with 85.4%.)

The revolution may have begun with the synthesis in 1938 of lysergic acid diethylamide (LSD) by Sandoz chemist Albert Hofmann. It was in 1943 that Hofmann discovered it was psychoactive; LSD went on to have a brief career in psychotherapy and the treatment of alcoholism, but it generated great scientific curiosity: Was its mechanism identical to that of schizophrenia?

In 1952, the Rhône-Poulenc Laboratories in Paris introduced the first antipsychotic (neuroleptic), chlorpromazine, of the phenothiazine class of three-ringed structures, which was brand-named Largactil in Europe, Thorazine in the United States. The staff of Paris psychiatry

Telegram: @medical_k

www.konkur.in

professor Jean Delay conducted the initial clinical trials. A number of other phenothiazine antipsychotics followed.

These two compounds—LSD and chlorpromazine—initiated the era of psychopharmacology. As Theodore Sourkes at McGill University, “a biochemist in psychiatry” as he called himself, put it later,

> The neuroleptic action of chlorpromazine and the psychodysleptic action of LSD … held out the promise, on the one hand, of a chemical treatment of mental disorders and, on the other, of exploring the possibility that schizophrenia was caused by a toxic substance. As a consequence, the fifties and sixties of the last century saw the introduction of chemical theories into psychiatry. (Sourkes TL. A biochemist in psychiatry: dropping in on the psychopharmacology era. In: Ban TA, Healy D, Shorter E, eds. *Reflections on Twentieth-Century Psychopharmacology.* Animula Publishing House; 2004:290–298.)

The proliferation of phenothiazines gave rise to the classification of “sedative” versus “incisive” neuroleptics, the former presumably for agitated patients, the latter for the withdrawn and retarded. Yet an analysis by Arthur Platz and coworkers at the Perry Point Veterans Administration Hospital in 1967 demonstrated that there was no difference in therapeutic profiles.

A more important distinction was effectiveness in patients with “positive symptoms” versus those with the apathetic withdrawal of “negative symptoms.” This was realized early. Fritz Freyhan, a German émigré considered one of the founders of psychopharmacology, observed in 1957, at the Second International Congress of Psychiatry in Zurich (the first was in Paris in 1950), “Two schizophrenic patients … may differ fundamentally, one being apathetic, the other excited and disturbed. Only the latter is a candidate for neuroleptic treatment.”

The new drugs marked the beginning of the end of the dominance of psychoanalysis. Heinz Lehmann, who conducted some of the first trials of chlorpromazine, said in a 1992 interview in the Bulletin of the Canadian Psychiatric Association,

> “The demonstration [was important] that psychotropic drugs, such as chlorpromazine … are actually effective, so effective that there remains no doubt even for the sturdiest psychoanalyst. Eventually they had to admit there is a

Telegram: @medical_k

www.konkur.in

physical substrate to schizophrenia and bipolar disorder, because certain physical substances, drugs, definitely are helpful in treating these disorders. (Lehmann H. Psychopharmacotherapy. In: Healy D, ed. *The Psychopharmacologists.* CRC Press; 2001:182.)

It was thus that psychiatry, after so many years out in the cold with psychoanalysis, was able to rejoin the rest of medicine. As Theodore Rothman, at the University of Southern California and Los Angeles Veterans Administration Hospital, said in 1960, at an organizational meeting that would lead to the founding of the American College of Neuropsychopharmacology (ACNP) the following year, “I can find no better keynote thought than that psychopharmacology has given us a common front with the basic medical sciences. Psychopharmacology is compelling us to re-integrate psychiatry into medicine.”

Back into medicine! But how did the new drugs work? The 1960s and 1970s were captivated by one-neurotransmitter-one-disease hypotheses.

Norepinephrine was first off the blocks. In 1965, in the American Journal of Psychiatry, Joseph Schildkraut of Harvard University proposed a “catecholamine hypothesis of affective disorders” (the neurotransmitter norepinephrine has a portion with a catechol structure). “Those drugs which cause depletion and inactivation of norepinephrine centrally produce sedation or depression, while drugs which increase or potentiate brain norepinephrine … generally exert an antidepressant effect in man.”

In 1968, Swedish pharmacologist Arvid Carlsson and coworkers at Gothenburg University noted in the Journal of Pharmacy and Pharmacology that the TCA imipramine blocked the reuptake of serotonin. “This action may be of importance for its antidepressive properties,” the authors said, initiating the serotonin hypothesis of depression.

It remained for dopamine, the third major biogenic amine neurotransmitter, to find its distinctive disease, and this occurred in 1976, as it was reported simultaneously by psychiatrist Solomon Snyder at Johns Hopkins University (in Science) and pharmacologist Philip Seeman at the University of Toronto (in Nature) that the

Telegram: @medical_k

www.konkur.in

potency of antipsychotic drugs in schizophrenia was a function of their ability to block the dopamine receptor.

The original scientific findings underlying these reports were never overturned, yet neurotransmission is a complex phenomenon, and the field quickly lost confidence in the specificity hypothesis—although, for decades, it was marketed relentlessly by the pharmaceutical industry. In 1978, J.L. Costa and coinvestigators at NIMH said of agents affecting serotonin metabolism, "… It certainly may be that a serotonin deficit state is not a prerequisite for therapeutic efficacy with any of these drugs." It is a shame that these hypotheses, so attractive for their theoretical elegance and simplicity, have now been largely discredited because psychopharmacology has never again been able to develop a unitary theory of drug action. At this writing, the brain remains a black box.

The Golden 50s

The year 1955 saw the launch of the first blockbuster drug in psychiatry, Wallace Laboratories' meprobamate, trade-named Miltown (and Equanil by Wyeth Laboratories, which licensed it from Wallace). Launched as a "tranquilizer," Miltown became almost a household word, opening up that large market for "nerves" between the antipsychotics and aspirin (see below). It was displaced by the benzodiazepines in the 1960s.

The monoamine oxidase inhibitors (MAOIs) were probably the first effective drug class, aside from opium, for serious depression. This awareness took a while dawning. The first MAOI, iproniazid (Hoffmann-La Roche's Marsilid), reached the market in 1951 for tuberculosis, but only in 1957 did the company begin to market it for depression. A series of other MAOIs followed, the most effective of which was probably phenelzine (Warner-Chilcott's Nardil), introduced in 1959 and still in use.

"Tranquilizers"

It was London physician Edward Sutleffe, who had a substantial practice of patients with "nervous irritation" among other diagnoses,

Telegram: @medical_k

www.konkur.in

who in his *Medical and Surgical Cases* in 1824, introduced into medicine the term “tranquilizer” in connection with a “tranquilizing” drug, “the juice of ground ivy,” that he was promoting. The word then slumbered in forgetfulness until 1953, when Ciba billed its new antihypertensive Serpasil (reserpine) as a “safe tranquilizer-antihypertensive.” Its calming effects were soon noted in psychological medicine, and the concept of “tranquilization” became the common denominator of a range of drugs from the antipsychotic chlorpromazine, introduced clinically in the United States in 1954, to the “antiphobic” agent benactyzine (Suavitil) that Merck brought out in 1957. The tranquilizers were thought an improvement upon the barbiturates because they had the same relaxing and composing effects without the daytime sedation. Yet soon, the concept of tranquilizer was ruptured by the introduction of the benzodiazepines after 1960 (see below). These “antianxiety” agents made the concept of tranquilization, which had lumped together antipsychotics and antinervous agents, seem outmoded.

Antipsychotics

The antipsychotic era began with the introduction of chlorpromazine in clinical trials in France in 1952 by the Rhône-Poulenc Laboratories. Called Largactil in Europe and Thorazine in the United States, chlorpromazine is thought to have initiated the era of psychopharmacology by prompting research into mechanisms. A slew of similar phenothiazine antipsychotics, also called neuroleptics, followed, including Smith Kline’s prochlorperazine (Compazine) in 1956 and thioridazine (Sandoz’s Mellaril) in 1958. Haloperidol (Janssen’s Haldol, a member of the butyrophenone class) entered practice in the United States in 1966.

Tricyclic Antidepressants

Owing to the close clinical observation of Swiss psychiatrist Roland Kuhn, Geigy Laboratories in Basel realized in 1957 that their new compound imipramine, a member of the tricyclic class, was active against “vital depression,” rather than being an antischizophrenic, as

Telegram: @medical_k

www.konkur.in

they had hoped (the antipsychotic market was just taking off). Marketed in the United States in 1959, imipramine (brand-named Tofranil) initiated a half-century of “antidepressant” treatment. News of the TCAs traveled quickly. At a conference at McGill University in 1959, Hans Hoff, who had become the professor of psychiatry in Vienna after the Second World War, admitted that he and psychoanalyst colleague Paul Schilder “had once tried to destroy the Kraepelinian nomenclature because of the feeling that psychodynamics and personal reactions were more important. Now, however, since a treatment had become available, diagnosis is essential.”

“Mood Stabilizers”

The mood-stabilizer era began with lithium in 1949. The term apparently surfaced for the first time in connection with a drug called aminophenylpyridone (Maltbie Laboratories’ Dornwal) in 1960. The phrase “mood stabilizer” did not, however, come into general use until Robert Post and colleagues at NIMH floated the “kindling hypothesis” in 1986, in the British Journal of Psychiatry: recurrent depressions could tip the brain into autonomous cycles of mood disorder. Other writers then proposed that various anticonvulsants could break into the kindling process and stabilize the hyperirritable brain. Aside from lithium, considered mood stabilizers were: derivatives of valproic acid called valproate and valpromide that medicinal chemist George Carraz at Berthier Laboratories in Grenoble synthesized in 1963; carbamazepine, patented in 1960 by Geigy, was introduced as a psychoactive compound in Japan, then discovered in 1980, by NIMH investigators to have effects in manic-depression. Lamotrigine was patented by the Wellcome Foundation in 1981 and inaugurated in 2003 in the United States by GlaxoSmithKline as Lamictal (“a stabilizing force”). The judgment of David Healy and colleagues in 2003, in Bipolar Disorders, was that “These agents are now thought of as being a homogeneous group [but] they may, in fact, be quite diverse agents all of which have a certain utility when used judiciously in manic depressive states.”

Telegram: @medical_k

www.konkur.in

After the 1950s, Relatively Few New Drug Classes

Benzodiazepines. The benzodiazepine story began with the marketing of Hoffmann-La Roche's Librium (chlordiazepoxide) in 1960. The numerous subsequent Roche benzos were also synthesized by medicinal chemist Leo Sternbach. So popular did the benzodiazepines become that entire "eras" in the 1960s and 1970s were named after such members of this class as Valium (diazepam, launched in 1963). With the exception of the SSRIs (selective serotonin reuptake inhibitors—see below), the benzodiazepines are probably the best-selling psychoactive drug class in history and moreover possessed genuine efficacy that later agents do not seem to have matched. Other benzos followed: clonazepam (Klonopin) reached the American market in 1975, and alprazolam (Upjohn's Xanax) was launched in 1981. A short-acting benzo, Upjohn's triazolam (Halcion), came out in the United States in 1982 and caused much controversy about discontinuation. There was a long period of fearfulness about addiction, although in 1983, in the Journal of the American Medical Association, Karl Rickels and associates at the University of Pennsylvania found the risks of withdrawal reactions in diazepam minimal for up to 8 months of use. In the new millennium, the benzos began a comeback. As Peter Roy-Byrne at the University of Washington School of Medicine put it in an editorial in 2014 in the American Journal of Psychiatry, "There is now general appreciation that, with careful clinical evaluation to rule out pre-existing addiction issues … benzodiazepines are safe and highly effective."

Selective Serotonin Reuptake Inhibitors (SSRIs). Marketed as agents that specifically inhibited the neuronal reuptake of serotonin, this drug class became the most successful in the history of psychiatry. Prozac (fluoxetine), which became a household word, was marketed by the Eli Lilly Company in Belgium in 1986, in the United States in 1988. Among the main SSRIs, there followed Pfizer's Zoloft (sertraline), marketed in 1992; paroxetine (Novartis's Paxil), introduced in the United States in 1993; and citalopram

Telegram: @medical_k

www.konkur.in

(Lundbeck's Cipramil), brought out in the United States in 1998 by Forest Laboratories (Celexa). The SSRIs were initially indicated for "depression," then for "anxiety," and by the time they all finally went off patent, countless were the indications for which this versatile drug class served.

Second-Generation Antipsychotics. The so-called "second-generation antipsychotics" (SGAs) have turned out not that different from the first generation and seem to be more a marketing concept. Yet, it might be noted that clozapine (Sandoz's Clozaril), deemed the most effective of them, is not exactly a new drug, having been patented in 1963. Leo Hollister's judgment in 1987 of the antipsychotics is of interest (Hollister led the Veterans Administration hospital in Palo Alto, California and is generally acknowledged as the dean of American psychopharmacology): "It is most discouraging that more effective pharmacotherapy for schizophrenia has not been developed in the more than three decades since the introduction of the first effective drugs." The current drugs, he said,

> are not curative; their ameliorative effects are often limited; many patients remain totally unresponsive; they are unpleasant to take, so that many patients are less than fully compliant; and they produce major side effects.

PEDIATRIC PSYCHIATRY

Psychiatrists have always been familiar with mental diseases in children. In 1809, Haslam reported cases of "insane children," such as a 7-year-old boy who was slow to develop and was placed on "the female side" of the hospital. Early on, psychotic illness in children was noted, sometimes as a distinctive form of what would later be called childhood schizophrenia, sometimes not. The "hebephrenia" that Ewald Hecker described in 1871 was commonly recognized in children. As Auguste Voisin, a staff psychiatrist at the Salpêtrière in Paris, commented in his 1883 textbook of "insanity in the young": "In partial insanity, the child may be manic [extatique], subject to ideas of homicide, arson, or theft, have deluded and demonic ideas … It is in the context of this partial insanity that we find the singular cases of

Telegram: @medical_k

www.konkur.in

childhood suicide, sometimes preceded by notes from which extreme exaltation shows through; thus a child of thirteen who hanged himself left behind a note saying, 'I bequeath my soul to Rousseau, my body to the earth.'"

Textbooks of child psychiatry were not slow in coming. In 1887, Hermann Emminghaus, professor of psychiatry in Freiburg, produced what was probably the first, *The Psychic Disorders of Childhood* (*Die psychischen Störungen des Kindesalters*). The foundational modern text of psychological approaches to disorders of childhood, *Lectures on the Psychopathology of Childhood* (*Vorlesungen über Psychopathologie des Kindesalters),* was written by August Homburger at the Heidelberg University Psychiatric Hospital in 1926. Among the first dedicated hospital divisions for children with mental illnesses was that at Bicêtre Hospice in Paris, which in 1838, received responsibility for the care of "children with mental retardation and epilepsy." In 1842, Édouard Séguin, who had developed a system for the care of children with retardation, took over the service, and after an interregnum, in 1851, Louis Delasiauve succeeded him. Désiré-Magloire Bourneville took it over in 1879, and in the course of the next decades, made Bicêtre into one of the most progressive children's psychiatric units in the world. (In 1892, he initiated a gymnastic competition, which became the unacknowledged forerunner of the Special Olympics.) In 1850, Séguin emigrated to the United States and initiated here the enlightened treatment of children who have what are now called intellectual disabilities.

The epidemic of encephalitis lethargica in the years 1917 to 1927 represented a strong inflection in the growing awareness of distinctive psychiatric illness in children, primarily because, unlike adults, the disease produced striking psychiatric changes in many children, transforming them from normal happy creatures into the "apache type" with severe behavioral problems. Said Leslie Colin Cook, who was a staffer at the West Park Mental Hospital in Epsom that had a center for such patients, in the Lancet in 1928, "Children of irreproachable family, hitherto of exemplary behavior and character, may in a very short period become guilty of every

Telegram: @medical_k

www.konkur.in

delinquency from mere naughtiness to cruelty and murder, and from mild bad habits to gross indecencies." This had happened, he said, in only one adult patient with the disease. The "EL" epidemic thus strengthened the interest of the field in children as a special kind of patient.

In the middle third of the 20th century, psychoanalysis became the doctrinal mainstay of child psychiatry. Freud himself did not see children and had relatively little experience with them. Psychoanalysis was first applied to the child, and adolescent population by Viennese educator and psychoanalyst August Aichhorn in his 1925 work Wayward Youth (Verwahrloste Jugend), about the ego structure of juvenile delinquency. Sigmund Freud's daughter Anna published her first book in 1927, An Introduction to the Technique of Child Analysis, and in 1936, The Ego and the Mechanisms of Defense. The Freud family fled to England after the Nazi Anschluss with Austria in 1938, and in 1941, Anna Freud helped found the Hampstead Nursery in London, where she treated children for several years. This gave way to the Hampstead Child Therapy Course and Clinic, which Anna directed until her death in 1982 (on her rivalry with Melanie Klein see above).

After the Second World War, the baton in child psychiatry passed to the United States. When the National Institute of Mental Health opened in 1949, the "quality of mothering" was put on the table—especially so by psychoanalysts such as Frieda Fromm-Reichmann at Chestnut Lodge in Maryland, who, in Psychiatry in 1948, had originated such concepts as the "schizophrenogenic mother." Among the leading child psychoanalysts in New York was Hungarian-born Margaret Mahler, who in 1950 cofounded the Masters Children's Center in Manhattan, where she developed the tripartite treatment model involving the mother in the child's treatment. Her most important work was *The Psychological Birth of the Human Infant* (1975).

Prompted by an interest in the ideas of Harvard psychologist Burrhus Frederick Skinner, in the late 1940s and 1950s, behaviorism started to become à la page. Psychoanalysis and behaviorism

Telegram: @medical_k

www.konkur.in

dominated pediatric psychiatry in the United States after the Second World War.

The child guidance clinics reached back to the First World War, and in 1948 they created an organization of clinics, the American Association of Psychiatric Clinics for Children, to develop standards of care and training. In 1953, the American Academy of Child Psychiatry was founded; in 1959, the American Board of Psychiatry and Neurology approved a 2-year child psychiatry residency to be grafted onto the regular training. The field received its own voice, The Journal of the American Academy of Child Psychiatry, in 1962, and a quarter-century later, in 1986, the Academy changed its name to the American Academy of Child and Adolescent Psychiatry.

In the heyday of psychoanalysis, “pills” were frowned on and great confidence placed in psychotherapy. Yet, the revolution in adult psychopharmacology in the 1950s had echoes in the pediatric world. “Psychopharmacology has revolutionized child psychiatry,” said Jovan Simeon, professor of psychiatry and child psychopharmacologist at the University of Ottawa, in 2004. Children had, of course, always been treated with such psychoactive agents as opium, mixed together with alcohol in laudanum (see above), which parents once routinely administered as a hypnotic. Treating children with psychopharmaceuticals entered the academic forum in 1937, when Charles Bradley, director of the Emma Pendleton Bradley Home in East Providence, Rhode Island, in the American Journal of Psychiatry reported the benefit of Benzedrine in “behavior problem” children, later defined as “hyperactive.” Loretta Bender, at Bellevue Hospital in New York, used chlorpromazine and amphetamine extensively in treatment. Systematic research in pediatric psychopharmacology began in 1958 when Leon Eisenberg at Johns Hopkins University received the first NIMH grant to study drugs in children, conducting the first controlled trial in pediatric psychopharmacology. This torch was then notably carried forward by Bender’s student Barbara Fish, first at Bellevue, then after 1972, at UCLA.

Such progress in pediatric psychopharmacology probably counts as an American “first.” There were a number of other American firsts,

Telegram: @medical_k

www.konkur.in

such as recognition by Lee Wachtel at the Kennedy Krieger Institute in Baltimore and Dirk Dhossche, in a 2010 article in Medical Hypotheses, of stereotypical movements in autism and intellectual disability as a sign of catatonia—and treatable with benzodiazepines and convulsive therapy.

As for diagnosis, disease classification in pediatric psychiatry has been in even greater turmoil than in general psychiatry, as psychoanalysis, behaviorism, and biologic approaches have dueled. Driven by parental concerns, clinicians are often pressed to make diagnoses such as ADHD. The fourth edition of DSM (DSM-IV) included the diagnosis "bipolar II disorder," characterized by depression plus "at least one hypomanic episode." Yet the field readily accepted outbursts of anger as a substitute for hypomania, touching off a virtual epidemic of "bipolar II" in the pediatric population, which the embarrassed drafters of DSM-5 were obliged to dial back in 2013, with the newly contrived "depressive" diagnosis "disruptive mood dysregulation disorder," said to be "included for children up to age 18 years who exhibit persistent irritability and frequent episodes of extreme behavioral dyscontrol." The classification of illness in children has thus still not stabilized.

NEW FORMS OF CARE

The asylum was a forbidding institution. Yet many patients outside its walls also required care, and over the years, these walls were slowly broken down.

Boarding patients out to local families achieved first this separation of care from the four walls of the institution. The earliest instance of this was seen at Gheel in the Brabant region of Belgium, where patient out-boarding went back to the 13th century. Yet the local farmers often had little tolerance for the antics of the patients, of whom they might board up to five at a time, and when Pliny Earle, of the Friends' Asylum in Frankford, visited there in the late 1830s (describing his travels in a book in 1841, he was shocked to find that the patients, "if mischievous or furious, are chained at the wrists and ankles. In every house, there is a ring beside the chimney, or

Telegram: @medical_k

www.konkur.in

attached to the beds, to which they may be chained." Boarding out was never widespread in the United States, possibly because the farms were too dispersed (unlike the compact Belgian villages). But in Scotland, around 1900, 23% of the asylum patients were boarded out.

There were other ways of breaking down the walls. The first psychiatric ward in a general hospital in the United States was established in 1902 at Albany Hospital. In 1885, Pennsylvania Hospital founded the first outpatient clinic, or very close to the first, in the United States, "so as to provide a dispensary service for the gratuitous treatment of persons suffering with incipient mental disease." (On these developments, see Henry Hurd's massive four-volume work in 1916 on the Institutional Care of the Insane.)

One of the unhappiest stories in U.S. psychiatry was that of "deinstitutionalization," under the influence of the antipsychiatric ideologies of the 1960s, discharging in-patients to a kind of community care that often turned out to be the care of the streets. This created an existential dilemma for psychiatry: what to do with the patients who were seriously ill? As Jonathan Cole said in an interview in 1996,

> We've got few places where we can serve the kind of patient who takes a long time to get better and where real rehabilitation is done. We tend to have more people who are home and crazy than we should have and nobody's going to pay for their treatment.

Beginning in the 1960s, this vast outpouring resulted in the closing of many of the classic asylums. In 1964, there were in the United States 255 public psychiatry beds per 100,000 population; by 2014, this figure had dropped to 11 per 100,000. The patients were supposed to be maintained in community settings on antipsychotics; in reality, they fed the vast ranks of the "homeless" and the imprisoned. In 2002, 64.2% of all inmates of local jails in the United States had a "mental health problem" (75.4% of the females). The figures were comparable for state and federal prisons. Donald Klein of Columbia University said later in an interview,

Telegram: @medical_k

www.konkur.in

> "It wasn't deinstitutionalization, it was trans-institutionalization. The patients, but not the money, were dumped on the cities. There was a sudden rise in homelessness. This led to federally supported 'community care,' staffed by therapy-minded psychologists. They had a psychiatrist who did little but sign bundles of prescriptions.

By one estimate, "There are 10 times as many mentally ill persons in prisons than in state hospital beds." David Rubinow at the UNC, who penned these lines in the American Journal of Psychiatry in 2014, concluded,

> It would appear that we somehow have achieved the complete reversal of policies initiated over 170 years ago to ensure the humane treatment of those with mental illness.

Yet history has good news as well. On the threshold of the new millennium, the role of psychiatry itself was slowly changing. Once seen as a band-aid for the "walking wounded," psychiatry was becoming the main resource for the seriously ill. In the United States from 2001 to 2002, 40% of patients identified in a national household survey with a serious mental problem would be seen by a psychiatrist. As for the rest of patients who formerly would have been "in therapy," psychiatry had ceased to be the main port of call: only 21% of those with moderate and 9% of those with mild disorders saw psychiatrists; they distributed themselves instead across the entire gamut of mental and medical health services, from "general medical" to "internet" (the main resource for 30% of those with "moderate" mental problems). Alarmingly, of those seeing a psychiatrist, 29% were said to have "no disorder." Readers will give a weary sigh. Yes, it's true: some things never change.

60 World Aspects of Psychiatry

Sam Gnanapragasam, B.Sc., M.B.B.S., M.R.C.Psych., Max Pemberton, M.B.B.S., B.Sc., M.R.C.Psych., Pedro Ruiz, M.D., Antonio Ventriglio, M.D., Ph.D., and Dinesh Bhugra, C.B.E., M.A., M.Sc., M.B.B.S., F.R.C.P., F.R.C.P.E., F.R.C.Psych., F.F.P.H., M.Phil., Ph.D., F.R.C.Psych. (Hon), F.H.K.C.Psych. (Hon), F.A.C.P. (Hon), F.A.M.S. (Singapore), F.I.M.S.A. (Hon)

Mental health disorders are highly prevalent across all regions of the world. These disorders represent a major source of disability and social burden. Even though treatments for these disorders are known and have been found to be efficacious in both high-, middle-, and low-income countries, this has not always translated into wider access, availability, and affordability of these interventions. Mental disorders remain undertreated worldwide, even when accounting for variation across societies and cultures. A treatment gap of more than 90% has been documented in some low-income countries, but even in high-income countries, high levels of gap remain. To complicate matters further, many countries do not have any mental health policies, and there are many others that have outdated policies originating in the 19th century. Consequently, both funding for treatment and research into mental health falls well below what is required or what is offered for physical disorders such as cancer and heart disease.

In recent years, there has been a focus on mental health provision around the world. This has led to the emergence of the global mental

Telegram: @medical_k

www.konkur.in

movement. Partly this is a response to rapid globalization, which has meant that people, resources, and ideas are moving much more rapidly than at any other time in the history of humanity. This has led to a clear acknowledgment that a number of factors at social and cultural levels are at play in influencing how distress is experienced and expressed. The thinking behind this movement is outlined in seminal literature such as the 2007 and 2011 Lancet Series on Global Mental Health and later revised 2018 Lancet Commission on Global Mental Health and Sustainable Development.

There remains a danger in that global mental health may follow the route of Anglo-American influences to be seen “dictating” to the low- and middle-income countries. Reassuringly, the latest commission report has reframed mental health within the Sustainable Development Goals framework and sought to establish mental health as a pillar of universal coverage. It has also sought to advocate for the use of public policies to protect mental health, including through investment and research innovation, as well as engagement with people with lived experience and strengthening of monitoring and accountability.

The international progress of collaboration has shifted considerably over the past two centuries. Initially, the rulers saw the vanquished as exotic natives who either did not have the mental capabilities to develop mental illness or, later, saw them as victims of biologic, social, and geopolitical factors. This gave way to international collaborative epidemiologic studies, which have contributed to the current understanding of both similarities and differences in etiology and outcomes of psychiatric disorders.

Although there have been many proclamations internationally recently about the importance of mental health, resources to deal with mental disorders and investing in public mental health have not followed the rhetoric. The contribution of funding to mental health care remains scarce and unequally distributed.

The authors prefer and choose the term “world psychiatry” in this chapter, as it reflects the real state of psychiatry at the present time. This chapter provides an overview of world psychiatry but focuses on epidemiology, the burden resulting from mental illness, the

Telegram: @medical_k

www.konkur.in

relationship between various illnesses, stigma, and the ethics of mental health care. There remain several serious questions in relation to the differences in rates and responses across different nations of the world. Some of these are discussed later in this chapter.

PREVALENCE AND BURDEN OF MENTAL DISORDERS WORLDWIDE

World Health Organization (WHO) estimates that more than one in four individuals worldwide develop one or more mental disorders during their lifetime. The Global Burden of Disease (GBD) project and studies that were undertaken provide specific data on multiple diseases from around the world. Herein Table 60–1, we report mental health prevalence findings from the 2017 study.

These findings in Table 60–1 are supported by a series of face-to-face community surveys conducted in 17 countries in Africa, Asia, the Americas, Europe, and the Middle East. These World Mental Health Surveys have included a total of 85,052 respondents. The lifetime prevalence of any mental disorder was found to be higher than 25% in 11 of 17 countries and higher than 15% in all countries except China and Nigeria, where prevalence rates were likely to be downwardly biased due to respondent reluctance to admit mental health problems. Whether these rates are genuinely low or whether these reflect reporting bias needs further exploration.

Not surprisingly, anxiety disorders were the most prevalent in 10 out of 17 countries, and mood disorders in 6 (Table 60–2). Anxiety disorders include agoraphobia, adult separation anxiety disorder, generalized anxiety disorder, panic disorder, posttraumatic stress disorder, social phobia, and specific phobia. Mood disorders include bipolar disorders, dysthymia, and major depressive disorder. Impulse-control disorders include intermittent explosive disorder and reported persistence in the past 12 months of symptoms of three child–adolescent disorders (attention-deficit/hyperactivity disorder, conduct disorder, and oppositional-defiant disorder). Substance disorders include alcohol or drug abuse with or without dependence. Following

Telegram: @medical_k

www.konkur.in

the *Diagnostic and Statistical Manual of Mental Health Disorders*, Fourth Edition (DSM-IV) norms, organic exclusions were excluded.

Lifetime co-occurrence of two or more mental disorders was quite common, so the sum of the prevalence rates across the various disorder types was between 30% and 50% higher than the proportion of people having at least one mental disorder. Survival analysis showed that the odds ratios for anxiety, mood, and substance use disorders were higher in recent compared to older cohorts. It is worth noting that even within the same geographical region, there appear to be major variations in the prevalence of DSM-IV/CIDI disorders.

[a]Anxiety disorders include agoraphobia, adult separation anxiety disorder, generalized anxiety disorder, panic disorder, posttraumatic stress disorder, social phobia, and specific phobia. Mood disorders include bipolar disorders, dysthymia, and major depressive disorder. Impulse-control disorders include intermittent explosive disorder, and reported persistence in the past 12 months of symptoms of three child–adolescent disorders (attention-deficit/hyperactivity disorder, conduct disorder, and oppositional-defiant disorder). Substance disorders include alcohol or drug abuse with or without dependence. In the case of substance dependence, respondents who met full criteria at some time in their life and who continue to have any symptoms are considered to have 12-month dependence even if they currently do not meet the full criteria for the disorder. Organic exclusions were made as specified in the *Diagnostic and Statistical Manual of Mental Health Disorders (DSM)*, 4th edition.
[b]Impulse disorders are restricted to age ≤39 (China, Ukraine, Nigeria) or to age ≤44 (all other countries).
[c]Adult separation anxiety disorder was not assessed.
[d]Specific phobia was not assessed.
[e]Bipolar disorders were not assessed.
[f]Intermittent explosive disorder was not assessed.
[g]Attention-deficit/hyperactivity disorder was not assessed.
[h]Conduct disorder was not assessed.
[i]Oppositional-defiant disorder was not assessed.
[j]Only alcohol abuse with or without dependence was assessed. No assessment was made of other drug abuse with or without dependence.

Reproduced with permission from Kessler RC, Aguilar-Gaxiola S, Alonso J, et al. The global burden of mental disorders: an update from the WHO World Mental Health (WMH) surveys. *Epidemiol Psichiatr Soc*. 2009;18(1):23–33. doi:10.1017/s1121189x00001421.

In the same series of studies, the 12-month prevalence showed similar variations. These findings illustrated regional and national variations. Once again, Nigerian respondents reported only 6% prevalence, with similar figures from Japan and China, but the rates were 4.5 times higher in the United States (see Table 60–3).

As shown in Table 60–4, when the association between 12-month severity and days out of role were compared, again, variations within regions and across nations were substantial. Once again, Nigeria and China had similar figures, whereas the United States showed the highest levels.

When the severity of these disorders was compared across nations and regions, similar variations emerged. China, Japan, Nigeria, and

Telegram: @medical_k

www.konkur.in

this time Italy showed lower levels of serious severity and higher levels of mild severity (see Table 60–5).

Using the disability scale for common chronic physical and mental health disorders, interesting differences emerged between developed and developing countries (see Table 60–6). Cancer, asthma, hypertension, and diabetes showed higher proportions of severe disability in developing countries, whereas neck and backaches, chronic pain, and headaches were more seriously disabling in developed countries. Bipolar disorders, depression, generalized anxiety disorders, panic disorders, and posttraumatic disorder–related disability was elevated in developed countries. This variation raises interesting questions about whether these are genuinely higher levels or are rather more commonly diagnosed.

Primary Care

Among people seen by primary health care professionals, more than 20% have one or more current mental disorders. In a study carried out by the WHO at 14 sites in Africa, Asia, the Americas, and Europe, the average current prevalence of any mental disorder was 24%, without consistent differences between low- and high-income countries. Not surprisingly, the most common diagnoses were those of depression (average 10.4%) and generalized anxiety disorder (average 7.9%). Female rates were 1.89 times higher than male rates for depression, but male rates were higher for alcohol-related disorders, so there was no sex difference in the proportion of people having at least one mental disorder. Physical ill-health and educational disadvantage were both significantly associated with a diagnosis of mental disorder.

Disability-Adjusted Life Years (DALYs)

In addition to measures of prevalence, understanding the impact of mental health globally must also take into account the morbidity associated with disabling mental health conditions. To quantify the burden of various diseases and injuries, the WHO, in collaboration with the Harvard School of Public Health and the World Bank,

Telegram: @medical_k

www.konkur.in

introduced in 1993 a new measure, the disability-adjusted life year (DALY). DALYs for a given disease or injury are the sum of the years of life lost due to premature mortality plus the years lost due to disability for incident cases of that disease or injury in the general population.

[a]No demographic controls were used.
[b]Significant association between severity and days out of role at the 0.05 level.
Reproduced with permission from Kessler RC, Aguilar-Gaxiola S, Alonso J, et al. The global burden of mental disorders: an update from the WHO World Mental Health (WMH) surveys. *Epidemiol Psichiatr Soc*. 2009;18(1):23–33. doi:10.1017/s1121189x00001421.

In the original estimates for the year 1990, mental and neurologic disorders accounted for 10.5% of the total DALYs lost due to all diseases and injuries. The burden of disease related to mental health disorders and related temporal change from 1990 to 2017 is shown by way of years lived with a disability (YLDs) in Table 60–7. When a comparison is made between years lived with disability due to depression between 2007 and 2017, it appears that the years have increased by 12.6% due to major depressive disorders and dysthymia by over 20%.

Telegram: @medical_k

www.konkur.in

The WHO estimates that one in four families worldwide has at least one member suffering from a mental disorder. The objective and subjective burden related to caring for people with severe mental disorders (in terms of disruption of family relationships; constraints in social, leisure, and work activities; financial difficulties; negative effect on physical health; feelings of loss, depression, and embarrassment in social situations; and the stress of coping with disturbing behaviors) have been reported to be substantial and significantly higher than that related to caring for people with long-term physical diseases such as diabetes, heart, kidney, or lung diseases. Cross-cultural differences have been reported in some dimensions of family burden: for example, relatives in the Mediterranean area compared with those in northern European countries were found to be more resigned and to use spiritual help more frequently as a coping strategy. They reported a greater level of reduction in social interests and lower levels of support from their social network.

Children and Adolescents

The mental health and well-being of young people are important to consider, given they represent a substantial proportion of the world's residents, with one in six people aged between 10 and 19. More than half of all mental health conditions are thought to start by the age of 14. However, most are not diagnosed or treated. The consequences of not treating mental health conditions during this period have profound ramifications as the impact extends into adulthood and limits functional abilities.

The prevalence of mental disorders among children and adolescents is difficult to evaluate because it is problematic to draw a reliable boundary between psychopathological phenomena and some manifestations that are part of normal development. Population surveys may help, but access to schools and clinics is extremely variable. Hence the accuracy of figures can be challenged. Many studies have used checklists compiled by parents and teachers, which are useful in detecting cases needing special attention but may not represent an appropriate basis for prevalence estimates.

www.konkur.in

Ten percent of all children and adolescents are thought to experience a mental disorder. In adolescents (aged 10 to 19), mental health conditions are thought to account for 16% of the GBD in that group. A GBD study among children between the ages of 5 and 14 found that mental disorders were among the leading causes of both DALYs in Europe, North America, and South America. They were in the top five causes in South East Asia, the Eastern Mediterranean, and the Western Pacific. Infectious diseases held a greater burden in Africa, and as such, mental health disorders were not among the top five causes of DALYs. It is likely that as low- and middle-income countries undergo epidemiologic transitions away from communicable disease, the share of disease burden related to mental health disorders will increase among young people.

Suicide

Telegram: @medical_k

www.konkur.in

According to WHO estimates, around 703,000 people died from suicide worldwide in the year 2019. This accounted for 1.3% of total deaths that year. The global age-standardized suicide rate was 9 per 100,000. Notably, there is a wide range between countries—less than 2 to over 80.0 deaths per 100,000. Globally, the age-standardized mortality rate was higher among men (12.6 per 100,000) compared to women (5.4 per 100,000). The suicide rate, therefore, was 2.3 times in men compared to women—was notably over 3 in high-income countries, 2.8 in upper-middle–income countries, 1.8 in upper-middle–income countries, and 2.9 in low-income countries. By and large, younger people and older adults had higher rates than middle-aged adults.

Around 77% of the suicides in 2019 occurred in low-and-middle-income countries. While this was the case and related to large overall populations, high-income countries had a higher age-standardized rate (10.9 per 100,000) compared to upper-middle–income countries (7.3 per 100,000), lower-middle–income countries (10.1 per 100,000) and low-income countries (9.9 per 100,000). Suicide rates varied by region (global average of 9.0 per 100,000): Europe, Africa, and South East Asia had higher rates at 10.5, 11.2, and 10.2 per 100,000, respectively. The Eastern Mediterranean region had the lowest rate at 6.4 per 100,000. In adolescents, the number who died by suicide in those countries is greater at 88%. Among young people aged between 15 and 29, suicide was the fourth leading cause of death.

*Percentage changes that are statistically significant.
Adapted from GBD 2017 Disease and Injury Incidence and Prevalence Collaborators. Global, regional, and national incidence, prevalence, and years lived with disability for 354 diseases and injuries for 195 countries and territories, 1990–2017: a systematic analysis for the Global Burden of Disease Study 2017. *Lancet*. 2018;392(10159):1789--1858. doi: 10.1016/S0140-6736(18)32279-7. https://creativecommons.org/licenses/by/4.0/

The age-standardized mortality rate decreased by 36% between 2000 and 2019. The rate decreased most, by 49%, in the Western Pacific Region. Although the overall decrease between 1990 and 2019 is promising and substantial, if the current trajectory continues, most countries will not meet the Sustainable Development Goals target of reducing suicide-related mortality by a third from 2015 to 2030.

Globally, the trends and varied patterns of suicidality reflect an interplay of different factors. These include socio-cultural, religious, and sociodemographic inter- and intra-country differences. In addition, economic circumstances, unemployment, exposure to violence, use of alcohol and drugs, patterns of mental disorder, and access to means of suicide (e.g., access to firearms) were all found to play a key role.

TREATMENT GAP AND PROJECTED POPULATION-LEVEL TREATMENT EFFECTIVENESS WORLDWIDE

Lifetime contact for treatment delay in various psychiatric conditions is shown in Table 60–8. Interestingly, common mental disorders showed longer delays. This is further confirmed in the 12-month service use by sectors (see Table 60–9).

The efficacy of pharmacologic and psychosocial treatments for mood, anxiety, psychotic, and substance-related disorders has been convincingly proved by clinical trials carried out in low- and middle-income as well as in high-income countries. However, the treatment gap is substantial for all mental disorders worldwide, in particular, in low-income countries.

In the World Mental Health Surveys, carried out in representative community samples in 17 countries in Africa, the Americas, Asia, Europe, and the Middle East, the proportion of lifetime cases of anxiety disorders making treatment contact in the year of disorder onset ranged from 0.8% in Nigeria to 36.4% in Israel. The proportion of cases making treatment contact by 50 years ranged from 15.2% in Nigeria to 95.0% in Germany. The median delay to treatment among cases eventually making contact ranged from 3 years in Israel to 30 years in Mexico (Table 60–10).

For Schizophrenia, a systematic review by Jääskeläinen and colleagues that was based upon 50 studies looking at outcomes found that only 13.5% of people with Schizophrenia (median) met clinical and social recovery criteria.

The proportion of lifetime cases of mood disorders making treatment contact in the year of disorder onset ranged from 6% in Nigeria and China to 52.1% in the Netherlands. The proportion of cases making treatment contact by 50 years ranged from 7.9% in China to 98.6% in France. The median delay to treatment among cases eventually making contact ranged from 1 year in Belgium, The Netherlands, Spain, and Japan to 14 years in Mexico (Table 60–11).

Telegram: @medical_k

www.konkur.in

The proportion of lifetime cases of substance use disorders making treatment contact in the year of disorder onset ranged from 0.9% in Mexico to 18.6% in Spain. The proportion of cases making treatment contact by 50 years ranged from 19.8% in Nigeria to 86.1% in Germany. The median delay to treatment among cases eventually making contact ranged from 6 years in Spain to 18 years in Belgium (Table 60–12).

Reprinted with permission from Wang PS, Angermeyer M, Borges G, et al. Delay and failure in treatment seeking after first onset of mental disorders in the World Health Organization's World Mental Health Survey Initiative. *World Psychiatry*. 2007;6(3):177–185.

In the World Mental Health Surveys, failure and delays in treatment-seeking were generally greater in low-income countries, older cohorts, men, and cases with earlier ages of onset. The earlier treatment contact of people with mood disorders might be partly due to the fact that these disorders have been targeted by educational campaigns and primary care quality improvement programs in several countries.

The Disease Control Priorities Project Report estimated the cost of a mental health care package consisting of outpatient treatment of schizophrenia and bipolar disorder with first-generation antipsychotics or mood stabilizers and adjuvant psychosocial interventions and treatment of depression and panic disorder in primary care with generic selective serotonin reuptake inhibitors. The cost per capita of the package was projected to be US$ 3 to 4 in sub-Saharan Africa and South Asia and US$ 7 to 9 in Latin America and the Caribbean. The addition of brief interventions by primary care physicians for high-risk alcohol users was projected to cost a further US$ 0.04 per capita in sub-Saharan Africa and South Asia and up to US$ 0.36 per capita in Central Asia and Latin America. Treatment of common mental disorders was reported to be in the same range of cost-effectiveness as antiretroviral treatment for HIV/AIDS, secondary prevention of hypertension, or glycemic control for diabetes.

RESOURCES FOR MENTAL HEALTH CARE WORLDWIDE

According to the Mental Health Atlas 2017, 79% of the 139 countries that responded had a standalone mental health policy or plan (i.e., a document of the government or ministry of health specifying the goals for improving the mental health situation of the country, the priorities among those goals, and the main directions for attaining them). This ranged from 72% in the African region to 90% in the South East Asia

Telegram: @medical_k

www.konkur.in

region (see Table 60–13). This is a notable improvement from findings in the Mental Health Atlas 2005, whereby Africa and Southeast Asia regions had 50% and 54.5%, respectively, of countries in their regions with mental health policy. Despite improvement, there remains a difference in the existence of policy and plans, and this reflects a number of factors. This could be attributed to the low importance of mental health in many countries and settings. It also has been explained on the basis of colonial rule, where the laws have not changed even after independence. 22 of the 36 countries that stated that they did not have standalone policies or plans for mental health had others have integrated policies for mental health as part of general health or disability policies. With regard to children and adolescent mental health, of the 78 countries that responded, only 46% had a plan or strategy.

Even where mental health plans are present, they have often not been supported by sufficient human and financial resources. Less

Telegram: @medical_k

www.konkur.in

than half of the countries surveyed had policies and plans that aligned with human rights conventions related to the participation of service users in decisions concerning them and stressed the importance of the transition from inpatient to community-based care. Specifically related to suicide, only a few countries had prevention strategies—approximately a third of high-income and upper-middle–income countries and 10% of low- and middle-income countries.

The Mental Health Atlas also considered the number of countries with mental health legislation and found that only 63% of countries (111 of 175 surveyed) had one. This varied from 44% in the African region to 77% in the European region (Table 60–14). Further, in some regions such as Africa and South East Asia, most countries did not have a dedicated authority or independent body to ensure compliance of mental health legislation with international human rights principles (Table 60–15).

Data from World Health Organization. *Mental Health Atlas 2017*. World Health Organization; 2018.

The median number of adult psychiatric beds per 100,000 population ranges from 2.5 in the African region to 59.7 in the European region (see Table 60–16). When considering availability related to the income status of countries, high-income countries had 52.6 beds per 100,000 compared to 1.9 beds per 100,000 in low-income countries. This significant disparity is ongoing despite the transition toward community-based residential care in high-income settings. Community care provision continues to lag in some regions, with a median rate of 437 visits per 100,000 in the South East Asia region compared to 8,073 in the European region (see Table 60–17) significantly. When considering rates related to income status of countries, high-income countries have 36 times the rate of adult outpatient visits compared to low-income countries (7,966 vs. 000220 per 100,000).

The global median mental health expenditure per capita in 2017 was 2.5 USD. Of the overall governmental health expenditure pie,

Telegram: @medical_k

www.konkur.in

mental health was less than 2% of the global median. There was noted to be significant variation between regions, with the European region spending 20 times that of the South East Asian and African regions. Notably, most of the mental health budget (approximately 80%) in low- and middle-income countries is spent in inpatient mental health hospitals. On the other hand, high-income countries spent approximately 43% on inpatient mental health hospitals.

Out-of-pocket payment is the most important method of financing mental health care in 43% of countries in Africa and 40% of countries in Southeast Asia, whereas it is not the primary method of financing mental health care in any European country (Table 60–18). Further, national health insurance and other reimbursement schemes did not cover care and treatment of severe mental disorders in two-thirds of countries globally.

Americas	1.38	3,071
Eastern Mediterranean	0.45	632
Europe	1.63	8,073
Southeast Asia	1.21	437
Western Pacific	2.08	693

Modified from World Health Organization. *Mental Health Atlas 2017*. World Health Organization; 2018.

The global median of health workers is 9 per 100,000. The median number of psychiatrists per 100,000 population ranges from 0.4 in South East Asia to 9.9 in Europe (Table 60–19). The median number of psychiatric nurses per 100,000 population ranges from 0.5 in Africa to 23.2 in Europe. The median number of psychologists working in mental health care per 100,000 population ranges from 0.1 in Southeast Asia and Africa to 5.4 in the Americas.

Nurses represent the single largest category of mental health workers, with between 30% and 50% of the overall workforce in the different regions. Notably, in the African and American regions, the number of psychiatrists and psychologists is greater than the number of nurses (see Table 60–19). Large-scale migration of psychiatrists and other mental health professionals from low- and middle-income to high-income countries, as part of the larger picture of migration of health professionals in general, has been consistently documented. India and some sub-Saharan African countries are the most important contributors to the mental health workforce in the United Kingdom, although the United Kingdom has higher rates of psychiatrists per

Telegram: @medical_k

www.konkur.in

million population compared to India and sub-Saharan African countries.

Even worse is the situation concerning child and adolescent mental health care. According to the Mental Health Atlas, only 46% of countries worldwide have a specific child and adolescent mental health policy. With regard to inpatient bed availability for this population, high-income countries have eight times the number of beds as low-income countries. In terms of outpatient care, there is a similarly striking discrepancy. The median in child and adolescent outpatient visits was 1,609 per 100,000 in high-income countries and 11 per 100,000 in low-income countries. With regard to workforce availability, there are less than 0.1 psychiatrists per 100,000 in all income groups except for high-income countries (1.19 per 100,000).

PRINCIPLES FOR MENTAL HEALTH PROGRAM DEVELOPMENT WORLDWIDE

Telegram: @medical_k

www.konkur.in

According to the WHO, the development of mental health programs worldwide should be guided by the following principles: (1) providing treatment in primary care, (2) making psychotropic medications available, (3) giving care in the community, (4) educating the public, (5) involving communities, families, and consumers, (6) establishing national policies and legislations, (7) developing human resources, (8) linking with other relevant sectors, (9) monitoring community mental health, and (10) supporting more research.

Providing treatment in primary care involves the inclusion of recognition and treatment of common mental disorders in training curricula of all health personnel, the provision of refresher training to primary care physicians, and the improvement in referral patterns in primary health care. Making psychotropic medications available includes ensuring the availability of essential drugs in all health care settings and, in high-income countries, providing easier access to newer psychotropic drugs under public or private treatment plans. Giving care in the community implies moving people with mental disorders out of prisons, downsizing mental hospitals and improving care within them, developing general hospital psychiatric units, and providing community care facilities.

Educating the public includes promoting public campaigns against stigma and discrimination; using the mass media to promote mental health, foster positive attitudes, and help to prevent mental disorders; and, in high-income countries, launching public campaigns for the recognition and treatment of common mental disorders. Involving communities, families, and consumers includes supporting the formation of self-help groups, ensuring the representation of communities, families, and consumers in services and policy making, and fostering advocacy initiatives.

Eastern Mediterranean	1.2	3.0	0.7	7.7
Europe	9.9	23.2	4.6	50
Southeast Asia	0.4	0.8	0.1	2.5
Western Pacific	1.6	7.9	1.3	10

Data from World Health Organization. *Mental Health Atlas 2017*. World Health Organization; 2018.

Establishing national policies and legislations includes revising legislations on the basis of current knowledge and human rights considerations and increasing the budget for mental health care. Developing human resources involves training psychiatrists and psychiatric nurses and, in middle- and high-income countries, creating national training centers for psychiatrists, psychiatric nurses, psychologists, and psychiatric social workers. Linking with other relevant sectors involves initiating school and workplace mental health programs, encouraging the activities of nongovernmental organizations in those areas, and, in high-income countries, initiating evidence-based mental health promotion programs in collaboration with other appropriate sectors.

Monitoring community mental health involves including mental disorders in basic health information systems, surveying high-risk population groups, instituting surveillance for specific disorders in the community, and, in high-income countries, monitoring the effectiveness of preventive programs. Supporting more research includes conducting studies in primary health care settings on the prevalence, course, outcome, and effect of mental disorders in the community; instituting effectiveness and cost-effectiveness studies for management of common mental disorders in primary health care; and, in high-income countries, carrying out research on the risk factors for mental disorders and on service delivery and investigating evidence on the prevention of mental disorders.

Telegram: @medical_k

www.konkur.in

The guiding principles proposed for the prevention of suicide worldwide include (1) reducing access to means of suicide (e.g., pesticides and firearms), (2) treating people with mental disorders, (3) improving media portrayal of suicide, (4) training primary health care personnel, (5) implementing school-based programs, and (6) developing hot lines and crisis centers.

BARRIERS TO CHANGE

The most significant barriers to the implementation of the foregoing principles worldwide, according to the WHO, include the following: (1) some stakeholders may be resistant to the changes, (2) health authorities may not believe in the effectiveness of mental health interventions, (3) there may be no consensus among the country's stakeholders about how to formulate or implement the new policy, (4) financial and human resources may be scarce, (5) other basic health priorities may compete with mental health care for funding, (6) primary care teams may feel overburdened by their workload and refuse to accept the introduction of the new policy, and (7) many mental health specialists may not want to work in community facilities or with primary care teams, preferring to remain in hospitals. The suggested solutions include (1) adopting an "all-winners approach" that ensures that the needs of all stakeholders are taken into account, (2) developing pilot projects and evaluating their effect on health and consumer satisfaction, (3) asking for technical reports from international experts, (4) focusing the implementation of the mental health policy on a demonstration area and performing cost-effectiveness studies, (5) linking mental health programs to other health priorities, and (6) showing primary care practitioners that people with mental disorders are already a hidden part of their burden and that the burden will decrease if these disorders are identified and treated.

STIGMATIZING ATTITUDES TOWARD PEOPLE WITH MENTAL DISORDERS

Telegram: @medical_k

www.konkur.in

Stigmatizing attitudes toward people with mental disorders are widespread in the general public and even among mental health professionals. Although it has been suggested that stigma may be less severe in Asian and African countries, a study carried out in India within the Stigma Programme of the World Psychiatric Association (WPA), in which 463 persons with schizophrenia and 651 family members were interviewed in four cities, reported that two-thirds of the respondents had suffered discrimination. Women and people living in urban areas were more stigmatized. Men experienced greater discrimination in the job area, whereas women experienced more problems in the family and social areas. In the family area, subtle discrimination in the form of decreased love, avoidance, rejection, distance, and excessive caution was frequently reported. In Ethiopia, among relatives of people with a diagnosis of schizophrenia or mood disorders, 75% reported that they had experienced stigma due to the presence of mental illness in the family, and 37% wanted to conceal the fact that a relative was ill. In a large survey carried out in China among people with schizophrenia and their family members, one-half of the respondents reported they had felt significantly stigmatized, and levels of stigma were found to be higher in urban areas. Stigmatization of people with mental disorders has been reported to be rare in Islamic countries.

Unlike people with physical disabilities, those with mental disorders are often perceived by the public to be in control of their disabilities and responsible for causing them. The view that “weakness,” “laziness,” or “lack of willpower” contribute to the development of mental disorders has been reported in several countries, including Turkey, Mongolia, and South Africa. The stigmatization of people with mental disorders may result in public avoidance, systematic discrimination, and reduced help-seeking behavior. In a survey carried out in 1996, in a probability sample of 1,444 adults in the United States, more than one-half of the respondents reported being unwilling to spend an evening socializing with, work next to, or have a family member marry a person with mental illness. Although most countries have some provision for disability benefits, people with mental illness are often specifically excluded from such entitlements.

Telegram: @medical_k

www.konkur.in

Moreover, mental disorders are frequently not considered in social and private insurance schemes for health care. Shame is reported to be one of the main barriers to seeking help for mental disorders in both developed and developing countries.

A review by Bhugra and colleagues of mental health policies from Commonwealth countries found that less than half of the countries had mental health policies. They also found that there was no equity between funding for mental and physical health disorders. In further analysis global analysis, the research group found that only 11% of countries surveyed had no restriction on voting for persons with mental disorders, with 36% barring voting altogether. Related to the right to marry, 30% of countries surveyed had no restriction, and 37% barred those with mental disorders from getting married. Further, in 12% of countries, mental disorders were grounds for divorce.

Strategies for addressing the stigmatization of people with mental disorders have been subdivided into three groups: protest, education, and contact. There is some evidence that protest campaigns may be effective in reducing stigmatizing behaviors against people with mental disorders. This activist approach may be more workable in some countries rather than in others. Education may promote a better understanding of mental illness, and educated people may be less likely to endorse stigma and discrimination. Even in rural settings in low- and middle-income countries, strategies can be put into place successfully. There is no doubt that certain environments produce higher levels of stigma. These authors reported that internalized stigma and social relationships provide a risk factor for social isolation, especially among patients with schizophrenia. Ungar and colleagues observed that various strategies are needed to deliver antistigma programs, and health care systems themselves need to be included in such efforts. There is no doubt that stigma, whether it is internal or external, will influence help-seeking. Corrigan and colleagues provide a reminder that **s**tigma remains a complex construct. The people who are affected by it and also demonstrate stigma include public, self, and structural components as mentioned above in health care structures. There is no doubt that it directly affects people with mental illness, as well as their support system,

Telegram: @medical_k

www.konkur.in

provider network, and community resources. These authors also remind readers that cultures influence stigma too. It is likely that cultures see illnesses and idioms of distress in different ways, and stigma may be generated and seen in different ways. Internalized stigma, too, may be affected by cultures, although Pérez-Garín and colleagues point out that well-being can play a major role in mediating stigma. The definitions and understanding of well-being itself can be influenced by cultures. Stigma by professionals themselves deserves further exploration. Poreddi and colleagues report that stigma in medical students can be reduced after they have been exposed to psychiatric teaching and training. It has been suggested that public policy needs to change in order to reduce stigma.

An inverse relationship between having contact with a person with mental illness and endorsing stigmatizing behaviors has been documented. Several recent programs, such as Time to Change in the United Kingdom, have demonstrated that talking with patients with psychiatric illness does lead to a positive change in people's attitudes and changes attitudes in a more positive direction.

RELATIONSHIPS BETWEEN MENTAL AND PHYSICAL DISEASES

Mortality due to physical illness is significantly increased in people with severe mental disorders compared with the general population. In a follow-up study carried out in the United Kingdom, the standardized mortality ratio (SMR) for natural causes in people with schizophrenia was 2.32 (i.e., mortality was more than twice higher than in the general population). The SMR for causes "avoidable by appropriate treatment" was 4.68. The highest SMRs were those for endocrine, nervous, respiratory, circulatory, and gastrointestinal diseases. Increased nonsuicide all-cause mortality has also been reported for bipolar disorder (SMR 1.9 for males and 2.1 for females) and dementia (relative risk [RR] 2.63; 95% confidence interval [CI] 2.17 to 3.21). A meta-analysis of 15 population-based studies of the effect of a diagnosis of depression on subsequent all-cause mortality yielded a pooled odds ratio of 1.7 (CI 1.5 to 2.0). Evidence from low-

Telegram: @medical_k

www.konkur.in

income countries is limited, but a large population study conducted in Ethiopia found high mortality rates for major depression (SMR 3.55, 95% CI 1.97 to 6.39) and schizophrenia (almost 5% per year).

People with mental illness seem not to have benefited from the recent favorable trends concerning mortality due to some physical diseases. In a longitudinal study conducted in Australia, a steady decline in the mortality rate due to ischemic heart disease was observed in the general population during the period from 1980 to 1998, dropping from 209 to 143 per 100,000 person-years in men and from 139 to 117 per 100,000 person-years in women. In contrast, the mortality rate remained approximately constant in male psychiatric patients (on average 280 per 100,000 person-years) and increased from 153 to 234 per 100,000 person-years in female psychiatric patients.

The prevalence of several physical diseases is increased in people with mental disorders compared with the general population. In a study carried out in the United States, people with psychotic disorders were found to be more likely than other people to develop diabetes, hypertension, heart disease, asthma, gastrointestinal disorders, skin infections, malignant neoplasms, and acute respiratory disorders. The rate was increased even when only patients without a concomitant substance use disorder were considered. In a study conducted in Nigeria, 55.2% of persons with schizophrenia-spectrum disorders referred for the first time to a psychiatric clinic had at least one physical disease, whereas, in persons with neurotic disorders, the rate was 11.8%. A strong prospective association has been documented between depression and coronary heart disease outcomes, including fatal myocardial infarction; on the other hand, the incidence of depression is increased after myocardial infarction, especially in the first month after the event. Depression also increases the risk of type II diabetes. In South Asia, an association between maternal perinatal depression and infant malnutrition and stunting at 6 months has been repeatedly reported.

People with severe mental disorders are at increased risk of contracting HIV infection, although prevalence rates vary substantially worldwide. Conversely, a large multicenter study conducted in sub-

Telegram: @medical_k

www.konkur.in

Saharan Africa, Asia, Latin America, Europe, and the United States reported a higher prevalence of depressive disorders among symptomatic HIV-seropositive people than in asymptomatic HIV-seropositive cases and seronegative controls. Evidence from both developed and developing countries shows that adherence to highly active antiretroviral therapy (HAART) is negatively affected by depression, cognitive impairment, and substance abuse.

The increased morbidity and mortality due to physical illness in people with severe mental disorders are first of all related to the increased prevalence in these people of several risk factors for cardiovascular, metabolic, and respiratory diseases, the most important of which are obesity, smoking, and alcohol and drug abuse.

In a study carried out in the United Kingdom, people with severe mental illness were significantly more likely to be obese (body mass index higher than 30) and morbidly obese (body mass index higher than 40) than the general population: The respective figures were 35.0 versus 19.4% and 3.7 versus 1.3%. When these figures were broken down by age and sex, 28.7% of men with severe mental illness aged between 18 and 44 years were obese, compared with 13.6% in the general population, and 3.7% versus 0.4% were morbidly obese. Even more striking were the figures concerning women of the same age: 50.6% versus 16.6% and 7.4% versus 2.0%, respectively.

In a meta-analysis of worldwide studies, a highly significant association between schizophrenia and current smoking was confirmed: The weighted average odds ratio was 5.9; it was 7.2 in males and 3.3 in females. The association remained significant when controls with severe mental illness were used (odds ratio 1.9). Heavy smoking and high nicotine dependence were also more frequent in people with schizophrenia than in the general population.

Patients with severe mental illness have also been reported to make poorer dietary choices and to be less physically active than the general population, but the relevant research evidence is not strong.

The increased risk of HIV infection in people with severe mental disorders may be explained by the high rates of sexual contact with multiple partners, the low levels of condom use, and the high

Telegram: @medical_k

www.konkur.in

prevalence of injected drug use and sexual contact with partners using injected drugs.

The access of people with mental illness to physical health care is reduced with respect to the general population. In the aforementioned study conducted in Australia, the SMR for ischemic heart disease was found to be 1.78 in men with schizophrenia. However, hospital admission for that disease was remarkably less common in both men and women with schizophrenia compared with the general population. Moreover, both men and women with schizophrenia were more than threefold less likely to receive revascularization procedures than the general population.

The quality of physical health care received by patients with severe mental illness is often worse than the general population. A study conducted in the United States found that adverse events during medical and surgical hospitalizations were significantly more frequent in patients with schizophrenia than in the other people, including infections due to medical care, postoperative respiratory failure, postoperative deep venous thrombosis or pulmonary embolism, and postoperative sepsis. All of these adverse events were associated with a significantly increased odds of admission to an intensive care unit and of death.

The decreased access of people with mental disorders to medical services has been related to several factors concerning the health care system. The effect of lack of insurance and the cost of care is well documented. In a study carried out in the United States, people with mental disorders were twice as likely as those without mental disorders to have been denied insurance because of a pre-existing condition (odds ratio 2.18). Having a mental disorder conferred a greater risk of having delayed seeking care because of cost (odds ratio 1.76) and of having been unable to obtain needed medical care (odds ratio 2.30).

Even when people with mental illness are seen by a doctor, their physical diseases often remain undiagnosed. Primary care providers may misperceive the medical complaints of people with mental disorders as “psychosomatic” or be unskilled or feel uncomfortable in dealing with this population. Underlying stigmatization may be

Telegram: @medical_k

www.konkur.in

involved. Moreover, during hospitalizations in medical and surgical wards, health care professionals may not be experienced in dealing with the special needs of patients with schizophrenia, may minimize or misinterpret their somatic symptoms, and may make inappropriate use of restraints or sedative drugs or fail to consider possible interactions of psychotropic drugs with other medications. On the other hand, many psychiatrists are unable or unwilling to perform physical and even neurologic examinations or are not up to date on the management of even common physical diseases.

To address this situation, the first step is raising awareness of the problem among mental health care professionals, primary care providers, and patients with schizophrenia and their families. The research information about the increased morbidity and mortality due to physical illness in people with schizophrenia should be appropriately disseminated.

Education and training of mental health professionals and primary care providers is a further essential step. Mental health professionals should be trained to perform at least basic medical tasks. They should be educated about the importance of recognizing physical illness in people with severe mental disorders and encouraged to become familiar with the most common reasons for underdiagnosis or misdiagnosis of physical illness in these patients. On the other hand, primary care providers should overcome their reluctance to treat people with severe mental illness and learn effective ways to interact and communicate with them; it is not only an issue of knowledge and skills but, most of all, one of attitudes.

Another essential step is the development of an appropriate integration between mental health and physical health care. A well-identified professional should be responsible for physical health care for each person with a severe mental disorder. Mental health services should be able to provide at least a standard routine assessment of their patients to identify or at least suspect the presence of physical health problems. Guidelines about the management of patients receiving antipsychotic drugs should be known and applied by all mental health services. Patients should be involved as much as possible; for instance, mental health professionals should encourage

Telegram: @medical_k

www.konkur.in

patients to monitor and chart their weight. Dietary and exercise programs should be routinely provided by mental health services. Flexible smoking cessation programs, which have shown some degree of success, could be considered in some settings.

ETHICAL ISSUES IN MENTAL HEALTH CARE

The protection and promotion of the human rights of people with mental disorders are emerging as a priority worldwide. In 1991, the United Nations issued Resolution 46/119 for the Protection of Persons with Mental Illness and the Improvement of Mental Health Care. In that resolution, the human rights of people with mental disorders and their right to treatment were codified for the first time in a UN document. The 25 principles covered the following areas: Definition of mental illness; protection of confidentiality; standards of care and treatment, including involuntary admission and consent to treatment; rights of persons with mental disorders in mental health facilities; protection of minors; provision of resources for mental health facilities; the role of community and culture; review mechanisms providing for the protection of the rights of offenders with mental disorders; and procedural safeguards protecting rights of persons with mental disorders. National governments were invited to promote the principles of the resolution by appropriate legislative, juridical, administrative, educational, and other provisions. However, violations of the human rights of people with mental disorders are still reported in many countries, and in a substantial number of low- and middle-income countries, patients in mental hospitals are physically restrained or secluded for long periods.

In Latin America, an influential document has been the Declaration of Caracas, adopted in 1990 by the Regional Conference on Restructuring Psychiatric Care in Latin America, which states that resources, care, and treatment for people with mental disorders should safeguard their dignity and human and civil rights and strive to maintain them people in their communities. The Declaration also states that mental health legislation should safeguard the human

Telegram: @medical_k

www.konkur.in

rights of people with mental disorders and that services should be organized so that these rights can be enforced.

In Africa, the Banjul Charter on Human and People's Rights, a legally binding document supervised by the African Commission on Human and People's Rights, in Article 5, addresses the right to respect for the dignity inherent in human beings and the prohibition of all forms of degradation, including cruel, inhuman, or degrading treatment.

According to the WHO, mental health legislation should cover the following issues: access to basic mental health care, least restrictive care, informed consent to treatment, voluntary and involuntary admission to treatment, competence issues, periodical review mechanism, confidentiality, rehabilitation, accreditation of professionals and facilities, and rights of families and caregivers.

In 1996, the WPA released the Madrid Declaration, which contains the ethical principles by which all national psychiatric societies are expected to abide. The Declaration includes seven general guidelines focusing on the aims of psychiatry: (1) psychiatrists must serve patients by providing the best therapy available consistent with accepted scientific knowledge and ethical principles and should devise therapeutic interventions that are the least restrictive to the freedom of the patient; (2) it is the duty of psychiatrists to keep abreast of scientific developments of their specialty and to convey updated knowledge to others; (3) the patient should be accepted as a partner by right in the therapeutic process, and the therapist–patient relationship must be based on mutual trust and respect, to allow the patient to make free and informed decisions; (4) treatment must always be in the best interest of the patient, and no treatment should be provided against the patient's will, unless withholding treatment would endanger life of the patient and/or those who surround them; (5) when psychiatrists are requested to assess a person, it is their duty to inform the person being assessed about the purpose of the intervention; (6) information contained in the therapeutic relationship should be kept in confidence and used exclusively for the purpose of improving the mental health of the patient; and (7) because psychiatric patients are particularly vulnerable research subjects,

Telegram: @medical_k

www.konkur.in

extra caution should be taken to safeguard their autonomy, as well as their mental and physical integrity.

INTERNATIONAL ORGANIZATIONS ACTIVE IN THE MENTAL HEALTH FIELD

There are many international organizations active in the mental health field. They include the WHO, which is the world's leading public health agency; some professional associations, among which the largest is the WPA, representing the psychiatric profession worldwide; and several organizations with a membership of users/families (e.g., the World Fellowship for Schizophrenia and the Global Alliance of Mental Illness Advocacy Networks [GAMIAN]) or of both mental health professionals and users/families (e.g., the World Federation for Mental Health [WFMH]).

The WHO is a UN agency with 193 member states, grouped into six regions (Africa, the Americas, European Mediterranean, Europe, Southeast Asia, and Western Pacific). It has a Department of Mental Health and Substance Abuse at its headquarters in Geneva and advisors for mental health in each of its regional offices. Its main functions are direction and coordination of international health work and technical cooperation with countries. Among the numerous recent WHO activities in the mental health field of special interest are the release of the *mhGAP Intervention Guide (mhGAP-IG)* for use in non-specialist health settings and the development of the report *Mental Health: New Understanding, New Hope*, which was completely devoted to mental health. It provided a summary of the current and projected impact of mental disorders and of the principles of mental health policy and service provision, as well as a set of recommendations for future action that can be adapted to the needs and resources of the various countries. Project Atlas aims to collect information on mental health resources across the world.

The WPA is an association of national psychiatric societies aimed at increasing the knowledge and skills necessary for work in the field of mental health and the care for the mentally ill. Its member societies number 145, spanning 121 countries and representing more than

Telegram: @medical_k

www.konkur.in

250,000 psychiatrists. The WPA organizes the World Congress of Psychiatry every 3 years. It also organizes international and regional congresses and meetings, and thematic conferences. It has over 70 scientific sections, which are aimed at disseminating information and promoting collaborative work in specific domains of psychiatry. It has produced several educational programs and a series of books and consensus statements (including the Declaration of Madrid on ethical principles for psychiatric practice). It has an official journal, *World Psychiatry*, which is produced in English, Spanish, and Chinese and is indexed in PubMed and ranked number 1 in Social Science Citation index. Subsequently, several books and information sheets have been published (a full list is available on the WPA website).

The WFMH is a multidisciplinary advocacy and education organization aimed at promoting the advancement of mental health awareness, prevention, advocacy, and best-practice recovery-focused interventions worldwide. Among its activities is the organization of the World Mental Health Day, observed every year on October 10, each time with a different theme.

FUTURE PERSPECTIVES

Several statements have been made by various groups and organizations about priorities for future action in the mental health field at the international level. Of special interest is the aforementioned 2018 Lancet Commission on Global Mental Health and Sustainable Development. In this document, four main foundational pillars are identified: (1) Mental Health is a global public good. In this statement, there is recognition that “all countries can be thought of as developing countries in the context of mental health”, (2) Health problems exist on a continuum, (3) Health is an individual and unique product of social and environmental influences, and (4) Mental health is a fundamental human right that requires a rights-based approach. It is a good step given the focus on wider systems and sustainable development. Indeed, it is explicit in stating that “Although ‘no health without mental health’ is an important aspiration,

Telegram: @medical_k

www.konkur.in

the era of ‘no sustainable development without mental health’ has begun.”

There are key recommendations made. These include:

1. Reframe mental health within the Sustainable Development Goal Framework
2. Establish mental health care as a pillar of Universal Health Coverage
3. Use public policies to protect mental health
4. Listen to and engage people with lived experience
5. Invest more in mental health
6. Use research to guide innovation and implementation
7. Strengthen monitoring and accountability

It is imperative that local explanatory models and idioms of distress are taken into account so that culturally appropriate, culturally sensitive, and culturally accessible models of service care are developed and delivered. In virtually every country around the world, there are insufficient human and material resources dedicated to the mentally ill and mental illness. In many countries, useful models of engaging the local community exist, and it will be helpful to learn how these work. Furthermore, models using e-mental health and telemental health should be employed, particularly in countries with large geographical areas.

Among the strategies proposed to place mental health on the public health priority agenda are the development and use of uniform and clearly understandable messages for mental health advocacy and the education of decision-makers within governments and donor agencies on the evidence concerning the public health significance of mental disorders and the cost-effectiveness of mental health care. Strategies suggested to improve the organization of mental health services include, among others, the provision of incentive arrangements to overcome vested interests blocking change and the organization of international technical support to learn from countries that have experienced successful mental health reform.

Telegram: @medical_k

www.konkur.in

To integrate the availability of mental health in general health care, it is proposed that mental health professionals be appointed and trained specifically for supporting and supervising primary health care staff. To promote the development of human resources for mental health, it is suggested that the professional and specialist workforce be increased and diversified and that the quality of mental health training be improved to ensure that it is practical and also occurs in community or primary care settings. Governments are asked to identify and scale up a priority package of service interventions and to increase mental health budget allocations, with the aim of attaining a minimum level of investment within 10 years of US$ 2 per capita in low-income countries and US$ 3 to 4 per capita in lower-middle–income countries.

International donors and governments of high-income countries, in particular those that are beneficiaries of the brain drain, are asked to place mental health on their priority agenda for health assistance to low- and middle-income countries. Finally, several indicators are proposed to monitor progress worldwide. From 2014 to 2017, WPA has launched an ambitious plan for the social justice for the mentally ill, focusing on domestic gender-based interpersonal violence; child physical and emotional abuse; prisoner mental health care; underserved populations such as asylum seekers, migrants, and refugees; those with intellectual disabilities, lesbian, gay, bisexual, and transgender individuals and older adult individuals and finally developing mental health promotion. Interestingly, World Medical Association is also focusing on child abuse and gender-based violence, and the two organizations are planning to work closely together. WPA is also working with other organizations to develop materials on peri-mental health as well as setting up the WPA-Lancet commission on psychiatry to explore the roles and responsibilities of psychiatrists in the first quarter of the 21st century.

FUTURE DIRECTIONS

This chapter has provided an overview of the burden of mental disorders worldwide, the treatment gap and the scarcity of resources

Telegram: @medical_k

www.konkur.in

for mental health care, especially in low- and middle-income countries, the WHO guidelines for the development of mental health programs, and the obstacles to their implementation, and several other issues of interest for world psychiatry. The discussion has been based as much as possible on data, although part of the data on world mental health is projections that may under- or overestimate the magnitude of the problems. Moreover, the threshold for the diagnosis of common mental disorders (e.g., depression and anxiety disorders) remains controversial, and although it can be argued that "subthreshold" conditions (not fulfilling current diagnostic criteria) might be a further neglected source of burden and disability, it can also be pointed out that some conditions fulfilling current diagnostic criteria might represent homeostatic reactions to adverse life events that are transient and do not require treatment. The threshold for the diagnosis of common mental disorders may be different in the various geographic and cultural contexts, making projections and international comparisons even more problematic. On the other hand, although several pharmacologic and psychotherapeutic interventions have been proved to be efficacious in various regions of the world, their feasibility and acceptability may not be the same worldwide, and current treatment guidelines may not be relevant to people living in several low- and middle-income countries. The same may apply to rehabilitation programs and models of community mental health care. The fact is that, although around 85% of the world's population lives in low- and middle-income countries, only a negligible proportion of research in the mental health field is conducted in those countries. Research-generated information is crucial to evaluate local needs, develop cost-effectiveness interventions, and monitor their implementation. Several initiatives are now addressing this research gap, and it can be hoped that a substantial revision of this chapter will be needed in the near future.

www.konkur.in

Persons and Events in Psychiatry

Person, Event, or Category	Country	Publications	Significance
Hippocrates of Cos (ca. 460–370 BCE)		*Hippocratic Writings*. Pelican Classics; 1978	Held that diseases are caused by imbalances in the four humors (blood, phlegm, yellow bile, black bile); melancholia is caused by excess black bile; hysteria is caused by wandering uterus; looked for natural causes of epilepsy, the "sacred disease"; advised dietary treatment of illness; the *Hippocratic Oath* established ideals of ethical conduct for physicians
Plato (427–347 BCE)	Greece	*The Dialogues of Plato*. Jowett B, trans. Random House; 1937	In *Timaeus, Phaedrus,* and *The Republic,* described two kinds of madness: Madness in which the appetitive soul lost the domination of the rational soul and madness inspired by the gods (divine madness)
Aristotle (384–322 BCE)	Greece	Ross WD: *Aristotle*. 6th ed. Routledge; 1995.	In *De Anima* and other psychological works, described the affections of desire, anger, fear, courage, envy, joy, hatred, and pity
Galen of Pergamon (130–200)	Asia Minor (Turkey) in the Roman Empire	*On the Affected Parts*. Siegel R, trans., ed. Karger; 1976	Consolidated the thoughts of Hippocrates, Plato, and Aristotle; his idea that depression was caused by an excess of black bile was influential until the 19th century
St. Augustine (354–430)	Tageste (Numidia, North Africa)	*Confessions*. Pusey EB, trans. Modern Library; 1949; Wills G: *Saint Augustine*. Lipper/Viking; 1999	His *Confessions* was the first book to center on psychological introspection
Avicenna (980–1037)	Persia	*A Treatise on the Canon of Medicine of Avicenna*. Luzac; 1930	His *Canon of Medicine* recognized that certain physical diseases were caused by emotional upsets and was widely read by Christian and Muslim physicians
Constanitus Africanus (ca. 1010–1087)	Carthage, North Africa	*Constantino l'Africano. Della melancolia*. 1959	His *Melancholia* made observations on delusional thinking, and, from the first medical school at Salerno, spread Galenic ideas on depression throughout western Europe
Petrarch (1304–1374)	Italy	*De remediis utriusque fortunae*	In his letters and *De remediis,* he developed a rhetoric that aimed to console and comfort the mentally disturbed, so (in the estimation of Stanley Jackson) "he made a significant contribution to the realm of consolatory and therapeutic wisdom"
Henry Kramer and James Sprenger (15th century)	Germany	*Malleus maleficarum (Witches' Hammer)* (1486)	Influential in causing the persecution of persons for witchcraft
Paracelsus (ca. 1493–1541)	Einsiedeln (Switzerland), then traveled Europe	Pagel W: "Disease and the stars. 'The animal in man' and lunacy. The psychiatry of Paracelsus." In: Paracelsus. 2nd rev. ed. Karger; 1982:150	Opposed the ideas of Galen; believed that psychiatric illness occurred when an individual's animal instincts were stimulated by the stars and that emotions caused physical illness (hence has been called an early "psychosomaticist"); treatments were mainly psychotherapy, but also included venesection, trephining, and sulfur
Juan Luis Vives (1493–1540)	Born in Spain; from the age of 16 years lived mainly in Holland and Belgium	*De anima et vita (Of Soul and Life)* (1538); Noreña CG. *Juan Luis Vives and the Emotions*. Southern Illinois University Press; 1989	Described for the first time the importance of psychological associations in forming emotions and in the remembering of past events
Johann Weyer (1515–1588)	Holland	*De Praestigiis Daemonum (The Deception of Demons)* (1563); reprinted in Mora G, ed. *Witches, Devils, and Doctors in the Renaissance*. Center for Medieval and Early Renaissance Studies; 1991	Criticizes the *Malleus* and refutes some of the prevailing beliefs in witchcraft

Juan Huarte de San Juan (ca. 1530–1592)	Spain	*The Examination of Men's Wits* (1575)	An early account of differences in temperaments and dispositions
Giambattista Porta (1535–1615)	Italy	*De humana physiognomia* (1586)	Gave to physiognomy the air of at least a pseudoscience
Felix Plater (1536–1614)	Switzerland	*Practice of Medicine* (1602); *Observations of Diseases Injurious to Body and Mind* (1614)	New classification of diseases based on symptoms, causes, and treatments; careful description of all known psychiatric and organic diseases; the first physician to separate medicine from philosophy and make it a branch of natural science; a pioneer in studying the behavior and neuropathology of the persons with mental handicaps
Robert Burton (1577–1640)	England	*The Anatomy of Melancholy* (1621)	The most famous book on psychiatry in the 17th century; a comprehensive presentation of all previous medical-psychological thought on melancholy, also drawing on the nonmedical literature of Western civilization
Paolo Zacchia (1584–1659)	Italy	*Questiones medico-legales* (1621–1635)	Held that a physician, rather than a priest or lawyer, should evaluate a patient's responsibility for disturbed behavior; the beginning of forensic psychiatry
Thomas Sydenham (1624–1689)	England	Dissertatio epistolaris… [1682]. In: The Entire Works of Dr. Thomas Sydenham Newly Made English (1742)	Gave a comprehensive picture of the many symptoms of hysteria, believing that in the form of hypochondriacal complaints, it could exist in men and that it was caused by disturbed animal spirits; his approach to classifying the causes of symptoms resembled the modern psychiatric endeavor of constructing atheoretical classifications of psychiatric illnesses
Thomas Willis (1621–1675)	England	*Two Discourses Concerning the Soul of Brutes* (1683)	Summarized what was known about major psychiatric illnesses; recognized differences in illnesses when there was gross brain disease and when the brain seemed normal, attributing the latter to disturbed animal spirits; attributed hysteria to disturbed animal spirits acting on the brain, not to a wandering uterus
Georg Ernst Stahl (1660–1734)	Germany	*Theoria medica vera* (1707), *De animi morbis* (1708)	Theory of animism; the soul, *anima*, maintains functions of body in health and disease; psychiatric illness is caused either by inhibitions of anima or diseases of the body
William Battie (1703–1776)	England	*A Treatise of Madness* (1758)	First physician who made insanity his full work, raised "the mad business" to a respected specialty, and first used "madness" in the title of his book
Boissier de Sauvages (1706–1767)	France	*Nosologia methodica* (1765)	Nosology divided diseases into classes based on symptoms; although speculative and artificial, it stimulated a rethinking of concepts of disease
John Aiken (1747–1822)	England	*Thoughts on Hospitals* (1771)	First book on hospitals in which "lunatic hospitals" were discussed
Franz Anton Mesmer (1734–1815)	Austria, France	*Memoire sur la découverte du magnetism animal* (1779)	Showed that when a mental therapist used the so-called animal magnetism, it could cure cases of psychiatric illness; led to the discovery of hypnosis
Vincenzo Chiarugi (1759–1820)	Italy	*Regulations of the Hospitals of Santa Maria Nuova and of Bonifazio* (1789)	One of the first attempts to treat the insane inmates of asylums humanely and without restraints
William Cullen (1710–1790)	Scotland	*Nosology, or a Systematic Arrangement of Diseases* (1800)	A great 18th century nosologist who first used the terms *neurosis* and *neurotic* to describe mental diseases
Philippe Pinel (1745–1826)	France	*A Treatise on Insanity in Which Are Contained the Principles of a New and More Practical Nosology of Mental Disorders* (1801)	Classified mental illness into four main forms and established a new, humane treatment for inmates of insane asylums, which he called "the moral treatment of insanity"
Johann Reil (1759–1813)	Germany	*Rhapsodies about the Application of Psychotherapy to Mental Disturbances* (1803)	The founder of rational psychotherapy, recognizing the therapeutic value of institutional surroundings, music, psychodrama, and occupational therapy; first used the word *psychiatry*, and founded the first psychiatric journal
Benjamin Rush (1745–1813)	United States	*Medical Inquiries and Observations upon the Diseases of the Mind* (1812); Farr C. Benjamin Rush and American psychiatry. *Am J Psychiatry*. 1994;151(Suppl):65	The most famous American physician of his time and the only physician to sign the Declaration of Independence; the first American author of a book on general psychiatry; and the father of American psychiatry. A vocal abolitionist, his legacy is complicated by the fact he owned a slave, William Grubber. Similarly, although he argued for the equality of African Americans, he also wrote that Black people's skin was a type of leprosy.
Thomas Sutton (1767–1835)	England	*Tracts on Delirium Tremens* (1813)	First description of alcoholic delirium tremens

William Tuke (1732–1822); Samuel Tuke (1784–1857), grandson of William Tuke; Daniel Hack Tuke (1827–1895), youngest son of Samuel Tuke; John Charles Bucknill (1817–1895)	England	Tuke S. Description of the Retreat, an Institution near York, for Insane Persons of the Society of Friends. York; 1813; Tuke DH, Bucknill JC. *A Manual of Psychological Medicine Containing the History, Nosology, Description, Statistics, Diagnosis, Pathology, and Treatment of Insanity*. 1858	W. Tuke founded the York Retreat for the moral treatment of mentally ill Quakers in 1796; S. Tuke's *Description of the Retreat* influenced asylum treatment in England, Europe, and the United States; the *Manual* of D. Tuke and Bucknill was the first comprehensive textbook of psychiatry
Joseph Adams (1756–1818)	England	*A Treatise on the Supposed Hereditary Properties of Diseases … Particularly in Madness and Scrofula* (1814)	First book on the hereditary properties of diseases; argued that it was not a disease that was inherited but a susceptibility to diseases; therefore, prevention and cure were possible
Franz Joseph Gall (1758–1828), Johann Gaspar Spurzheim (1776–1832)	Austria, Germany	*The Physiognomical System of Drs. Gall and Spurzheim; founded on an anatomical and physiological examination of the nervous system in general and of the brain in particular* (1815)	The beginning of phrenology: Mapping parts of the brain, defining their psychological functions, and making psychological and psychotherapeutic predictions
Johann Christian Heinroth (1773–1843)	Germany	*Disturbances of the Mind* (1818); Hansen LA. Metaphors of mind and society: The origins of German psychiatry in the revolutionary era. *Isis*. 1998;89:387; Cauwenbergh LS. *J Chr A Heinroth* (1773–1843) a psychiatrist of the German Romantic era. *Hist Psychiatry*. 1991;2:365	First systematic textbook of psychiatry that attempted to formulate an actual clinical system of psychotherapy; the first to use the word *psychosomatic* and the first to hold a chair in psychological medicine at the University of Leipzig
Robert Gooch (1784–1830)	England	*An Account of…Diseases Peculiar to Women* (1829)	First account of postpartum psychosis
James Cowles Pritchard (1786–1848)	England	*A Treatise on Insanity and Other Disorders Affecting the Mind* (1835)	Standard textbook of psychiatry covering all of the literature on all known diseases; described moral insanity, later called *psychopathic personality*
Jean Etienne Dominique Esquirol (1782–1840)	France	*Mental Maladies: A Treatise on Insanity* (1838)	Coined the term *hallucination*, described "idiocy," classified insanities into monomania (partial insanity) and general delirium, and recognized both emotional and organic causes of illness; one of the authors of a comprehensive law providing an asylum for every department of France
Isaac Ray (1807–1881)	United States	*Treatise on Medical Jurisprudence of Insanity* (1838)	Founded American forensic psychiatry
James Braid (1795–1860)	England	*Neurypnology; or, the Rationale of Nervous Sleep* (1843)	Entirely separated hypnotism from animal magnetism and began the study of hypnotic phenomena
Daniel M'Naghton (1813–1865)	England	West DJ, Walk A, eds. *Daniel M'Naghton: His Trial and the Aftermath*. London Gaskell Books; 1977	Suffering from persecutory delusions, M'Naghton murdered the secretary of a government official in 1843; at his murder trial, he was ruled not guilty by reason of insanity and was committed to an insane asylum for the rest of his life; the "M'Naghton rule" has influenced English and American legal criteria for acquittal on the basis of insanity
Wilhelm Griesinger (1817–1868)	Germany	*Mental Pathology and Therapeutics* (1845)	Proclaimed that psychiatric diseases are brain diseases and that psychiatry had become a medical specialty
Jacques-Joseph Moreau de Tours (1804–1884)	France	*Du haschich et de l'aliénation mentale* (1845)	Described the effects of his taking hashish, and became the first psychiatrist to experience a drug-induced psychosis
Diversity, Equity, Inclusion, and Justice	United States	Samuel Cartwright presents a report to the Medical Association of Louisiana in 1851	Dr. Cartwright proposed the mental illness of "drapetomania," or the dissatisfaction of slaves with their condition and their resulting tendency to run away. He also coined the term dysaesthesia aethiopica, a supposed disorder that explains the lack of work ethic among slaves.
Walter Cooper Dendy (1794–1871)	England	Psychotherapeia, or the remedial influence of mind. *J Psychol Med Ment Pathol*. 1853;6:268	First introduced the term *psychotherapeia* (psychotherapy), which he defined as prevention and remedy of disease by psychical influence and which he predicted would become valuable in psychiatry

www.konkur.in

Jean-Pierre Falret (1794–1870), Jules Baillarger (1809–1890)	France	Baillarger J. La folie à double forme. *Bull Acad Imp Med.* 1853–1854;19:340; Falret JP. La folie circulaire. *Bull Acad Imp Med.* 1853–1854;19:382; Pichot P. The birth of the bipolar disorder. *Eur Psychiatry.* 1995;10:1	Baillarger and Falret called bipolar disorder "double insanity" and "circular insanity"; in 1899, Kraepelin named this illness *manic-depressive psychosis*
Thomas Kirkbride (1809–1883)	United States	*On the Construction, Organization, and General Arrangements of Hospitals for the Insane* (1854)	Set a standard for mid-19th century care of the chronically insane that commands respect today
John Conolly (1794–1866)	England	*The Treatment of the Insane without Mechanical Restraints* (1856)	Conolly's work for the nonrestraint system marked the success of a movement that began with Pinel and created a new approach to treating insanity throughout the civilized world
George Robinson (1821–1875)	England	*On the Prevention and Treatment of Mental Disorders* (1859)	Introduced the idea of looking beyond the precincts of the asylum to prevent mental illness
Gustav Theodor Fechner (1801–1887)	Germany	*Elements of Psychophysics* (1860)	Established the relationship between the intensity of stimuli and sensory reactions; called the founder of experimental psychology
Benedict-Augustin Morel (1809–1873)	France	*Traité des maladies mentales* (1860)	Presented cases of insanity and other mental illnesses caused by inherited "mental degeneration" that became worse from one generation to the next
Thomas Laycock (1812–1876)	England	*Mind and Brain* (1860)	Mentioned unconscious functional activity of the brain but did not further develop the idea
Forbes B. Winslow (1810–1874)	England	*On Obscure Diseases of the Brain and Disorders of the Mind* (1860)	First to mention psychical diagnostic tests (psychological tests) and the psychiatric interview
Ewald Hecker (1843–1909)	Germany	Die Hebephrenie. *Arch Pathol Anat Physiol.* 1871:52	First description of "hebephrenia" (later a subgroup of dementia praecox)
Karl Kahlbaum (1828–1899)	Germany	*Die Katatonie oder das Spannungsirresein* (Berlin, 1874)	First description of catatonia (later a subgroup of dementia praecox)
George Miller Beard (1840–1883)	United States	*A Practical Treatise on Nervous Exhaustion (Neurasthenia)* (1880)	Neurasthenia—a disease of mental and physical exhaustion—replaced the diagnosis of hypochondriasis; it became prevalent in the American and European upper classes from approximately 1870 to 1920
Richard von Krafft-Ebing (1840–1902)	Germany	*Psychopathia sexualis* (1886); Oosterhuis H. *Stepchildren of Nature: Kraft-Ebing, Psychiatry, and the Making of Sexual Identity.* C University of Chicago Press; 2000	Described cases of homosexuality and sexual perversions, claiming that some were caused by degeneration, and coined the terms *sadism, masochism,* and *sexual bondage; Psychopathia* was respected by lawyers and scientists, and it founded the science of sexology
Pierre Janet (1859–1947)	France	*L'automatisme psychologique: Essai de psychologie experimentale sur les formes inferieures de l'active* (Paris, 1889); van der Kolk BA, van der Hart O. Pierre Janet and the breakdown of adaptation in psychological trauma. *Am J Psychiatry.* 1989;146:1530	Showed that severe traumatic experiences caused two types of dissociative symptoms—*hysteria,* with dissociations of feelings or memories related to the experiences, and *psychasthenia,* with obsessions, phobias, and anxieties; the first systematic attempt to show how the mind can dissociate in the face of severe trauma
Herman Emminghaus (1845–1904)	Germany	*Psychic Disturbances of Childhood* (1887)	First textbook of child psychiatry
Jean-Martin Charcot (1825–1893)	France	Owen ARG. *Hysteria, Hypnosis, and Healing: The Work of JM Charcot.* Garrett Publications; 1971; by Goetz C, Bonduelle M, Gelfand T. *Charcot: Constructing Neurology.* Oxford University Press; 1995	In 1882, became the first professor of diseases of the nervous system at the University of Paris, helping to institutionalize neurology as a medical specialty and making Paris an international center for neurologic studies; although he erroneously believed that only hysterics could be hypnotized, he fully delineated and classified the protean manifestations of hysteria, and he was the first to give a psychological account of hysteria and show that some of its symptoms are the result of ideas that dominated the mind of the hysteric
Georges Gilles de la Tourette (1857–1904)	France	Etude sur une affection nerveuse caractérisée par l'incoordination motrice accompagnée d'echolalie et coprolalie. *Arch Neurol* (Paris). 1885;ix:19, 158; Yorston G, Hindley N, trans. and intro: Study of a nervous disorder characterized by motor incoordination with echolalia and coprolalia. *Hist Psychiatry.* 1998;9:97; Kushner HI. *A Cursing Brain? The Histories of Tourette Syndrome.* Harvard University Press; 1999	Described a syndrome of involuntary movements and echolalia and coprolalia in nine patients, seven of whom were at the Paris Hôpital de la Salpêtrière, where he was a resident neurologist in training; Jean-Martin Charcot, director of the Salpêtrière and France's leading neurologist, then sanctioned the use of de la Tourette's name for the syndrome

Cesare Lombroso (1835–1909)	Italy	*Genius and Insanity* (1864), *The Delinquent Man* (1876), *The Female Offender* (1893)	Emphasized the study of the individual personality, which gave rise to pathographies—psychopathologically oriented biographies; his books on delinquent men and women stimulated a school of criminal anthropology that engendered the science of criminology
Emil Kraepelin (1856–1926)	Germany	Kraepelin E. *Psychiatrie: Ein Lehrbuch für Studerende und Aerzte*. 6th ed. (1899); *Memoirs*. Springer-Verlag; 1987	Divided the major psychoses into two groups: Dementia praecox, which deteriorated to dementia, and manic-depressive psychosis, which did not deteriorate
John Hughlings Jackson (1834–1911)	England	*Selected Writings of John Hughlings Jackson* (London, 1931–1932)	From 1870 to 1900, developed the thesis that psychiatric symptoms are a regression from higher functions that are the products of evolution; the symptoms resulted from activating more primitive functions
Sigmund Freud (1856–1939)	Austria	*The Interpretation of Dreams* (1900), *Three Essays on the Theory of Sexuality* (1905), *Introductory Lectures on Psychoanalysis* (1915–1917)	Discovered the manifestations of the unconscious and how to use them in treating psychiatric patients; described infantile sexuality and how it accounted for adult sexual dysfunctions; founded psychoanalysis
Morton Prince (1854–1929)	United States	*The Dissociation of a Personality* (1905)	Early account of a multiple personality; emphasized techniques of hypnosis and manifestations of the unconscious
Clifford Beers (1876–1943)	United States	*A Mind That Found Itself* (1908)	Account of experiences in psychiatric hospitals that stimulated the mental hygiene movement in the United States
Eugen Bleuler (1857–1939)	Switzerland	*Dementia Praecox or the Group of Schizophrenias* (1911)	Coined the term *schizophrenia* and described its symptoms
Alfred Binet (1857–1911)	France	*A Method of Measuring the Development of the Intelligence of Young Children*, with T. Simon (1911); English translation, 1913	Developed the first practicable intelligence test for children; it has become the prototype for subsequent tests of intellectual ability in children and adults
Hideyo Noguchi (1876–1928)	United States	Noguchi H, Moore JW. A demonstration of the *Treponema pallidum* in the brain in cases of general paralysis. *J Exp Med*. 1913;17	The definitive demonstration, after a century of controversy, that the syphilitic organism causes general paresis; the first time that the cause of a major psychosis became known
Alfred Adler (1870–1937)	Austria	*Study of Organ Inferiority and Its Psychical Compensations* (1917); Stepansky PE. *In Freud's Shadow: Adler in Context*. Analytic Press; 1983	First psychoanalytic defector from Freud; founded the school of individual psychology and coined the terms *life style* and *inferiority complex*
Hermann Rorschach (1884–1922)	Switzerland	*Psychodiagnostik* (1921)	Inkblot test revealed unconscious motivations and ego defenses against them and was used for psychiatric diagnosis; it stimulated the development of other projective diagnostic tests
Julius von Wagner-Jauregg (1857–1940)	Austria	de Rudoli G. *Therapeutic Malaria* (1927); Wagner-Jauregg J. The history of the malaria treatment of general paresis. *Am J Psychiatry*. 1994;151(Suppl):231; Brown EM. Why Wagner-Jauregg won the Nobel Prize for discovering malaria therapy for general paresis of the insane. *Hist Psychiatry*. 2000;11:371	During the decade 1917–1927, showed that general paresis patients underwent remissions when malaria was induced; for the time, it was the most successful organic treatment of a psychosis; for that, he became, in 1927, the first psychiatrist to receive the Nobel Prize; in the 1940s, penicillin became the treatment of choice for paresis
Otto Rank (1884–1939)	Austria, France, United States	*The Myth of the Birth of the Hero* (1909), *The Trauma of Birth* (1924), *Will Therapy* (1936); Lieberman EJ. *Acts of Will: The Life and Work of Otto Rank*. Free Press, Macmillan; 1985	Made important contributions to Freudian psychoanalysis by showing how a person's wishes and fantasies influenced the formation of human myths; breaking with Freud, Rank formed his theory of how the experience of birth influenced a person's mental development and then his technique of will therapy
American Board of Psychiatry and Neurology (ABPN)	United States	Freeman W, Ebaugh F, Boyd D Jr. The founding of the American Board of Psychiatry and Neurology, Inc. *Am J Psychiatry*. 1959;115:769	In 1934, a group of prominent American psychiatrists and neurologists founded the ABPN, comprising equal numbers of psychiatrists and neurologists, with separate qualifications and examinations for psychiatrists and neurologists; the qualifications for psychiatrists included 3 years of study of psychiatry after an internship, and 2 years of hospital practice in psychiatry; the original purpose of the ABPN was, in the words of Walter Freeman, "to create standards of ethical practice and professional competence based on adequate fundamental education in the field"; since its founding, it has maintained these standards while keeping abreast of advances in information and technology

www.konkur.in

Henry A. Murray (1893–1988)	United States	*Thematic Apperception Test*. Harvard University Press; 1943	The Thematic Apperception Test, originated in 1935, is a method used for uncovering conscious and unconscious dominant themes in a person's mental life
Organizational Psychiatry/ Diversity, Equity, Inclusion, and Justice	United Kingdom	The Indian division of the Royal Medico-Psychological Association is formed in 1935.	
Charles Bradley (1902–1979)	United States	Bradley C. The behavior of children receiving Benzedrine. *Am J Psychiatry*. 1937:577; Gross MD. Origin of stimulant use for treatment of attention deficit disorder. *Am J Psychiatry*. 1995;152:298	The first physician to record the successful treatment of what came to be called attention-deficit disorder in children with stimulant medications
Cure of pellagra	United States	Roe D. *A Plague of Corn: The Social History of Pellagra*. Cornell University Press; 1973	Pellagra is a niacin-deficiency disease manifested by diarrhea, dermatitis, and dementia; in the South, it was caused by removal of niacin in the milling of corn and was a major cause of dementia; in 1912, Joseph Goldberger (1874–1929), of the U.S. Public Health Service, proved that pellagra was caused by absence of a pellagra-preventive factor in the diet; in 1937, that factor was identified as niacin; since then, with niacin-enriched diets, pellagra has largely vanished; pellagra has also occurred in other countries whose staple grain is maize (American corn)
Genetics of schizophrenia	Germany, United States	Rüdin E. *Studien über Verebung und Entstehung geistiger Störungen. I. Zur Vererbung und Neuetstehung der Dementia Praecox*. [*Studies on the Heredity and Genesis of Mental Diseases. I. On the Heredity and New Formation of Dementia Praecox*.] Berlin: Verlag von Julius Springer; 1916; Kallman FJ. *The Genetics of Schizophrenia*. JJ Augustin; 1938; Rainer JD. The contributions of Franz J. Kallmann to the genetics of schizophrenia. In: Cancro R, Dean SR, eds. *Research in the Schizophrenic Disorders: The Stanley R. Dean Award Lectures*. Vol. 2. Spectrum; 1985	Rüdin (1874–1952) and Kallman (1897–1965) showed that schizophrenia was transmitted by recessive genes (although they differed over how these genes exerted their effects); Kallman first worked under Rüdin in the Max Planck Institute of Psychiatry in Munich, then studied the incidence of schizophrenia among the siblings and descendants of 1,087 hospitalized schizophrenic patients in two Berlin hospitals; when he emigrated to the United States in 1936, he brought the German manuscript of his book on these patients; it was translated into English in 1938 and became a pioneering work; Kallman spent the rest of his life working at the New York Psychiatric Institute, where he established the first full-time medical genetics department in a U.S. psychiatric institution
ECT	Italy	Abrams R. The treatment that will not die. *Psychiatr Clin North Am*. 1994;17:525; Berrios G. The scientific origins of electroconvulsive therapy: A conceptual history. *Hist Psychiatry*. 1997;8:105	Two Italian psychiatrists, Ugo Cerletti (1897–1963) and Lucio Bini (1908–1964), first used ECT in Rome in 1938 to produce convulsions that alleviated symptoms in a schizophrenic patient; it was then found to be more effective in mood disorders than in schizophrenia, and although its use has declined because of psychotropic drugs, modified forms of ECT are used today
Karen Horney (1885–1952)	Germany until 1932, then United States	*The Neurotic Personality of Our Time* (1937), *New Ways in Psychoanalysis* (1939), *Neurosis and Human Growth: The Struggle Toward Self-Realization* (1950); Paris B. Karen Horney: *A Psychoanalyst's Search for Self-Understanding*. Yale University Press; 1994	Opposed Freud's theory of the castration complex in women and his emphasis on the oedipal complex and sexuality as influencing neurosis; argued that neurosis was influenced by the culture of the society in which one lived
Adolf Meyer (1866–1950)	Switzerland until 1893, then United States	Meyer A. A short sketch of the problems of psychiatry. *Am J Insanity*. 1896–1897;53: 538; Lidz T. Adolf Meyer and the development of American psychiatry. *Am J Psychiatry*. 1996;123:320; Adolf Meyer. In: Havens L, ed. *Approaches to the Mind*. Little, Brown.	From 1912 to 1940, the dominant figure in American psychiatry; his concept of psychobiology viewed the patient as a biologic and psychological unity who became ill because of internal pathology and maladaptations to the environment; he treated patients with medical and nonmedical therapies in community clinics; his work has become part of present-day American psychiatry
Constitution, personality, and mental illness	Germany, United States	Kretschmer E. Body Build and Character (1922); Sheldon WH. Varieties of Human Physique (1940)	Kretschmer (1888–1964) and Sheldon (1899–1977) postulated that thin, asthenic individuals were prone to introversion, schizoid tendencies, and schizophrenia, whereas individuals who were short and round were predisposed to be extroverts and had cyclothymic personalities and manic depression; there are many exceptions to these postulates

Führer decree (1939)	Germany	Lifton RJ. The Nazi doctors. In: "Euthanasia": *Direct Medical Killing*. Basic Books; 1986: Chapter 2; Gallagher HG. *By Trust Betrayed: Patients, Physicians, and the License to Kill in the Third Reich*. Henry Holt; 1990; Annas GJ, Grodin MA, eds. *The Nazi Doctors and the Nuremburg Code. Human Rights in Human Experimentation*. Oxford University Press; 1992	In October 1939, soon after the outbreak of World War II, a Führer decree ordered doctors to kill patients who had incurable medical illnesses (this grew out of the Nazi doctrine of preserving racial purity by eliminating those who were "biologically unfit"); during the course of the war, approximately 270,000 mental patients were killed by physicians and medical personnel; Henry Friedlander postulated in *The Origins of Nazi Genocide: From Euthanasia to the Final Solution* (1995) that these medical killings, which began in 1940, served as a stimulus and practical model for the Nazi genocide of Jews and Gypsies that began in 1941
MMPI	United States	Buchanan R. The development of the Minnesota Multiphasic Personality Inventory. *J Hist Behav Sci*. 1994;29:148	The MMPI, developed by S. R. Hathaway (1903–1984) and J. C. McKinley (1891–1950) at the University of Minnesota during the early 1940s, became the most widely used and researched psychological personality measurement device; a revised version of the MMPI, MMPI-2, was published in 1989; in 1999, a third edition of MMPI-2 was published, containing the results of new research studies along with a new chapter on forensic applications of MMPI-2
Leo Kanner (1894–1981)	Austria, United States	Child Psychiatry. Springfield, IL: CC Thomas; 1935; Autistic disturbances of affective contact. *Nerv Child*. 1943;2:217	The first English-language textbook of child psychiatry and a pioneering description of what Kanner later called "early infantile autism"
Melanie Klein (1882–1960), Anna Freud (1895–1982)	Central Europe, then England	Klein M. *The Psychoanalysis of Children* (1932); Kernberg O. Melanie Klein. In: Kaplan HI, Freedman AM, Sadock BJ, eds. *Comprehensive Textbook of Psychiatry*. 3rd ed. Williams & Wilkins; 1980; Grosskurth P. *Melanie Klein: Her World and Her Work*. Knopf; 1986; Freud A. *The Ego and the Mechanisms of Defence* (1936), *The Psychoanalytic Treatment of Children* (1946), A short history of child analysis. *Psychoanal Study Child*. 1966;21:7; Young-Bruehl E. *Anna Freud: A Biography*. Summit Books; 1988	Klein and A. Freud were pioneers in originating different concepts of child psychoanalysis; Klein's concepts of the "paranoid-schizoid and depressive positions" of very young children has influenced child psychiatry and the treatment of adult borderline and psychotic patients; A. Freud formulated a group of basic concepts of child psychoanalysis and extended the ego psychology work of her father, Sigmund Freud, by delineating the ego defenses, including "identification with the aggressor"
Helene Deutsch (1884–1982)	Europe until 1935, then United States	*The Psychology of Women*, 2 vols. (1945); some forms of emotional disturbance and their relationship to schizophrenia ("As If"). In: Deutsch H, ed. *Neuroses and Character Types*. International Universities Press; 1965: Chapter 20; Roazen P. *Helene Deutsch: A Psychoanalyst's Life*. Anchor Press/Doubleday; 1985	For several decades the most comprehensive Freudian view of the life cycle of women; her most famous clinical concept was the "as if" personality: An apparently normal person who gives a good semblance of adaptation to reality, yet is actually devoid of genuine emotion
Ivan Petrovich Pavlov (1849–1936), Andrew Salter (1914–1996)	Russia, United States	Pavlov IP. *Lectures on Conditioned Reflexes*. 2 vols. International Publishers; 1941; Babkin, BP. *Pavlov: A Biography*. University of Chicago Press; 1949; *Salter A. Conditioned Reflex Therapy*. Farrar, Straus; 1949	From 1903 to 1936, Pavlov showed how conditioned reflexes influence normal and pathologic thought; Salter then applied conditioned reflex therapy to psychiatric patients by postulating that neuroses result from an excess of cortical inhibition and by emphasizing assertion training; his therapy became one trend in the development of behavioral therapy
NMHA (1946), NIMH (1949)	United States	Grob GN. *From Asylum to Community: Mental Health Policy in Modern America*. Princeton University Press; 1991: Chapters 2–4. Romano J. Reminiscences: 1938 and since. *Am J Psychiatry*. 1990;147:785	Congressional passage in 1946 of the NMHA provided American psychiatry for the first time with generous funds for psychiatric education and research, and led to the creation of the NIMH in 1949, with goals of research in schizophrenia and training of mental health personnel
Organizational Psychiatry	India	The Indian Psychiatric Society is Established in 1947	
Popular Media	United Statues	The Snake Pit, by Mary Jane Ward is published in 1946. A movie adaptation is released in 1948, sparking a call for reforms to the U.S. state psychiatric hospital system.

Erik H. Erikson (1902–1994)	Europe; United States since 1930s	*Childhood and Society* (1950), *Identity and the Life Cycle* (1959); Friedman LJ. *Identity's Architect: A Biography of Erik H. Erikson*. Scribner; 1999; Wallerstein R, Goldberger L, eds. *Ideas and Identities: The Life and Work of Erik Erikson*. International Universities Press; 1999	Restated Freud's concepts of infantile sexuality, developed concepts of adult identity and identity crisis, and applied psychoanalytic concepts to U.S. cultural life and political history; his *Young Man Luther: A Study in Psychoanalysis and History* (1958) influenced the writing of psychohistory
Carl Rogers (1902–1987)	United States	*Client-Centered Theory* (1951)	Showed that in many patients there existed constructive mental forces that had been previously unrecognized and unemployed and that a therapist, through the use of insight and catharsis, could aid a patient to use these forces to make beneficial changes in his or her life; the approach marked the beginning of a shift of psychotherapy from physicians and psychoanalysts to clinical psychologists and psychiatric social workers
Donald Winnicott (1896–1971)	England	Winnicott D. Transitional objects and transitional phenomena [1951]. In: *Collected Papers: Through Paediatrics to Psychoanalysis*. Tavistock, 1958; Kohon H. *The British School of Psychoanalysis: The Independent Tradition*. Yale University Press; 1986; Rodman FR. *Winnicott: Life and Work*. Perseus; 2003	Observed the transitional objects to which a young child becomes attached, which provide a bridge between the child's inner and outer worlds and then influence the development of play, creativity, and cultural life in general; a member of the "independent tradition" in British psychoanalysis (i.e., independent from the views of Klein and Anna Freud), which, instead of emphasizing instincts, stressed object relations
Jean Delay (1907–1987), Pierre Deniker (1917–1999)	France	Delay J, Deniker P. Le traitement des psychoses par une méthode neurolytique dérivée de l'hibernothérapie. *C R Congrés Med Alién Neurol France*. 1952;50:497; Thuillier J. *Ten Years That Changed the Face of Mental Illness*. Martin Dunitz; 1999; Healy D. *The Creation of Psychopharmacology*. Harvard University Press; 2002	In their first reports on chlorpromazine to French psychiatrists, Delay and Deniker emphasized that patients were quieted like animals in hibernation and called the drug "hibernotherapie"; chlorpromazine and related compounds then came into wide general use for treating patients with psychosis and helped to reduce the number of asylum patients
Harry Stack Sullivan (1892–1949)	United States	Sullivan HS. *The Interpersonal Theory of Psychiatry*. Perry HS, Gawel ML, eds. WW Norton; 1953; Perry HS. *Psychiatrist of America: The Life of Harry Stack Sullivan*: The Belknap Press of Harvard University Press; 1982	The interpersonal theory holds that a person's impulses and strivings cannot be studied in and for themselves, but only as they appear in an interpersonal situation; Sullivan also coined the terms *participant observer* (therapists must be aware of the overt and covert behavior of the patient and their own reactions); *consensual validation* (the awareness of patient and therapist of the terminology they use); and *parataxic distortion* (the patient's distortion of the real person of the therapist necessitated by the patient's personality structure)
Egas Moniz (1874–1955), Walter Freeman (1895–1972)	United States, Europe	Valenstein ES. *Great and Desperate Cures: The Rise and Decline of Psychosurgery and Other Radical* Treatments for Mental Illness. Basic Books; 1986; Pressman JD. *Last Resort: Psychosurgery and the Limits of Medicine*. Cambridge University Press; 1998	During the late 1940s and early 1950s, under the influence of Moniz and Freeman, many patients with severe psychoses and OCD were treated by lobotomy—destruction of the white matter of the frontal lobes of the brain; no adequately controlled studies were ever performed; some patients improved, but others experienced irreversible personality deterioration; with the advent of the psychotropic drugs, the use of lobotomies markedly declined
Advent of the double-blind test	United States	Gold H, Kwit NT, Otto H. The xanthines (theobromine and aminophylline) in the treatment of cardiac pain. *JAMA*. 1937;108:2173; Hampson JL, Rosenthal D, Frank J. A comparative study of the effect of mephenesin and placebo on the symptomatology of a mixed group of psychiatric outpatients. *Bull Johns Hopkins Hosp*. 1954;95:170	In the double-blind test, a drug or a procedure and a placebo are compared in such a way that neither the patient nor the therapists involved in treatment know which preparation is being administered; this type of test was first used in medicine in 1937 to evaluate the efficacy of the xanthines in relieving cardiac pain; it was used in psychiatry in 1954 to evaluate the efficacy of mephenesin, and then lithium, in relieving different psychiatric illnesses; since 1954, the main psychiatric use of double-blind tests has been to evaluate the efficacy of psychotropic drugs and psychiatric procedures

www.konkur.in

Carl Gustav Jung (1875–1961)	Switzerland	*Psychological Types* (1921), *Two Essays on Analytical Psychology* (1912–1928), *The Structure and Dynamics of the Psyche* (1916–1952), *The Archetypes and the Collective Unconscious* (1934–1955); Kirsch T. *The Jungians: A Comparative and Historical Perspective*. Routledge; 2000	After separating from Freud, Jung founded the school of analytical psychology, developing new psychotherapeutic approaches and concepts of the unconscious (especially the collective unconscious) and new personality types, such as introvert and extrovert
Antidepressant drugs	Switzerland, United States	Kuhn R. The treatment of depressive states with an iminodibenzyl derivative (G 22355). *Swiss Med J*. 1957;87:1135; Loomer HP, Saunders JC, Kline NS. A clinical and pharmacodynamic evaluation of iproniazid as a psychic energizer. *Psychiatr Res Rep*. 1957;8:129; Healy D. *The Antidepressant Era*. Harvard University Press; 1997; Kuhn R. *Hist Psychiatry*. 2007;17:253	The first reports of the effectiveness of a tricyclic drug, imipramine (G 22355), and an MAOI, iproniazid (Marsilid), in the treatment of depression
B. F. Skinner (1904–1990), Joseph Wolpe (1915–1997)	United States, South Africa	Skinner BF. *Science and Human Behavior*. Free Press; 1953; Wolpe J. *Psychotherapy by Reciprocal Inhibition*. Stanford University Press; 1958	Skinner's operant conditioning and Wolpe's reciprocal inhibition were important trends in the development of behavioral therapy
Development of child psychiatry	United States	Lewis M, ed. *Child and Adolescent Psychiatry: A Comprehensive Textbook*. 2nd ed. Williams & Wilkins; 1996: Chapters 120 (Rafferty F. Effects of health delivery systems on child and adolescent mental health care); 123 (Schowalter J. Recruitment, training, and certification in child and adolescent psychiatry in the United States); 127 (Bernstein D. The discovery of the child: A historical perspective on child and adolescent psychiatry)	After 1945, child psychiatry developed as a psychiatric specialty that separated from adult psychiatry with the formation of the American Academy of Child Psychiatry (1953) and the American Board of Child Psychiatry (1959)
Karl Jaspers (1883–1969)	Germany	*General Psychopathology* (1st ed., 1913; 7th ed., 1959) (English trans., 1963)	Delineated different mental states to show the meaningful connections between different thoughts (without looking for an underlying cause), and to have empathy for both the felt mental state of the patient and the observing mental state of the physician; this view influenced psychotherapy in general and became part of the tenets of existential psychotherapy
Kurt Schneider (1887–1967)	Germany	Schneider K. *Psychopathic Personalities*. Cassell; 1958; Schneider K. *Clinical Psychopathology*. Grune Stratton; 1959	In clinical psychiatry, Schneider carried forward—with modifications—the descriptive and phenomenologic approaches of Kraepelin and Jaspers; his work included clinical and phenomenologic descriptions of the experience of delusions and hallucinations and a classification and definition of the primary and secondary symptoms of schizophrenia; *Psychopathic Personalities* described a number of abnormal personality types that he encountered in practice and differentiated from psychotic states.
Michel Foucault (1926–1984)	France	*Histoire de la folie* (1961); English trans., *Madness and Civilization: A History of Insanity in the Age of Reason*. Pantheon; 1965	Gave an unconventional history of attitudes toward insanity in Europe from 1500 to 1800; believing that sanity and insanity are largely conditioned by history and the model on which a given society operated, he postulated that creation of the asylum and moral therapy at the end of the 18th century was not progress but an attempt to force insane people to conform to existing social values, and that the authority of the psychiatrist who headed the hospital did not derive from his knowledge of the science of human behavior, but from his association with the power of society; although important historians showed that many of his facts and interpretations contained serious errors, his ideas continue to be debated; *Histoire de la folie* is, in the words of Porter, "easily...the single most influential text of psychiatric historiography in the second half of the century"

Benzodiazepine drugs	United States	Cohen IM. The benzodiazepines. In: Ayd FJ Jr, Blackwell B, eds. *Discoveries in Biological Psychiatry*. Ayd Medical Communications; 1984:130	The benzodiazepines were developed by the pharmaceutical company of Hoffmann-La Roche; chlordiazepoxide (Librium) was first marketed in 1960 and diazepam (Valium) in 1963; the drugs became widely prescribed as anxiolytic drugs in cases of nonpsychotic anxiety
Haloperidol in the treatment of Gilles de la Tourette syndrome	France	Seignot JN. Un cas de maladie des tics de Gilles de la Tourette guéri par le R-1625. Ann Med Psychol. 1961; cxix: 578; The case of Gilles de la Tourette syndrome: A condition of nervous tics cured by R. 1625. *Hist Psychiatry*. 1997;8:434	Reported the cure of one case of Tourette syndrome with haloperidol in 1961, when the drug was an experimental compound (R. 1625); However, the patient treated had previously undergone a lobectomy, which easily could have affected his response; since then, haloperidol has become probably the most commonly prescribed drug for Tourette syndrome
Joint Commission on Mental Illness and Mental Health (1955–1961)	United States	*Action for Mental Health* (1961); Community Mental Health Centers Act of 1963	*Action for Mental Health* recommended psychiatric deinstitutionalization of the care of persons with mental illness by shifting their care from large mental hospitals into community mental health clinics; deinstitutionalization became a reality with the passage of the Community Mental Health Centers Act of 1963
Popular Media	United States	The Myth of Mental Illness, by Thomas Szasz is published.	The book was a powerful critique of contemporary psychiatric practice and is considered a classic.
Rene Spitz (1887–1974)	Europe, then United States	*The First Year of Life: A Psychoanalytic Study of Normal and Deviant Development of Object Relations*. International Universities Press; 1963	Showed that, when separated from their mothers during the first year of life, some infants exhibited overt depression, characterized by *marasmus* (a pining away of a physically healthy child), which could result in death; Spitz also observed that indiscriminate smiling at moving faces and masks began between the ages of 2 and 6 months, and that smiling at familiar faces occurred only after age 6 months
Classification of mental disorders	United States	DSM-I prepared by the Committee on Nomenclature and Statistics of the APA, G.N. Raines, chair (Mental Hospital Service, Washington, DC, 1952); DSM-II prepared by the Committee on Nomenclature and Statistics of the APA, E. Gruenberg, chair (APA, Washington, DC, 1968); Grob G. Origins of DSM-I: A study in appearance and reality. *Am J Psychiatry*. 1991;148:421	DSM-I replaced several outdated classifications of mental disorders and for the first time provided a glossary of definitions of psychiatric conditions; it was not universally accepted in the United States and most other countries; although DSM-II diagnosed new disease entities, including disorders of childhood and adolescence, its diagnostic methods and criteria were criticized by several leading psychiatrists
Epidemiologic evidence for the genetic transmission of schizophrenia	United States, Denmark	Rosenthal D, Kety SS, eds. *The Transmission of Schizophrenia*. Pergamon Press; 1968:235 (Wender PH, Rosenthal D, Kety SS. A psychiatric assessment of the adoptive parents of schizophrenics), 345 (Kety SS, Rosenthal D, Wender PH, Schulsinger F. The types and prevalence of mental illness in the biological and adoptive families of adopted schizophrenics), and 377 (Rosenthal D, Wender PH, Kety SS, Schulsinger F, Welner J. Schizophrenics' offspring reared in adoptive homes); Kety SS, Wender PH, Jacobsen B, Ingraham LJ, Jansson L. Mental illness in the biological and adoptive relatives of schizophrenic adoptees: Replication of the Copenhagen study in the rest of Denmark. *Arch Gen Psychiatry*. 1994;51:442	A study of 5,483 Danish adoptees found that 507 had been admitted to a psychiatric hospital, and 33 were classified as having schizophrenic disorders; an equal number of matched adoptees who had no history of psychiatric disorders were identified for comparison; of the 150 biologic relatives of the schizophrenic adoptees, 8.7% had a diagnosis of schizophrenia, compared with 1.9% of the 156 biologic relatives of the nonschizophrenic adoptees; that significant difference indicated that genetic factors were important in the transmission of schizophrenia; these statistics were then replicated by statistics from the rest of Denmark; this method of study was later used to show that other psychiatric disorders (bipolar disorder, suicide, psychopathy, felonious behavior, alcoholism, and hyperactivity in children) were caused by genetic factors; it stimulated molecular geneticists to search for the molecular genetic basis of those disorders
Lithium therapy for psychotic excitement	Australia, Denmark, United States	Cade J. Lithium salts in the treatment of psychotic excitement. *Med J Aust*. 1949;36:349; Schou M, Juel-Nielsen N, Stromgren E, Voldby H. The treatment of manic psychoses by the administration of lithium salts. *J Neurol Neurosurg Psychiatry*. 1954;17:250; Schou M. Forty years of lithium treatment. Arch Gen Psychiatry. 1997;54:9; J Schioldann: Mogens Abelin Schou (1918–2005)—Half a century with Lithium. *Hist Psychiatry*. 2007;17:247	After the Australian psychiatrist Cade reported that lithium quieted manic patients, the Danish psychiatrist Schou confirmed that finding in a double-blind study; Schou then developed lithium therapy for manic-depressive illness; because of lithium's toxicity and because many psychiatrists questioned its therapeutic effectiveness, it was not approved until 1970 by the U.S. Food and Drug Administration

William H. Masters (1915–2001), Virginia E. Johnson (1925–)	United States	*Human Sexual Response* (1966), *Human Sexual Dysfunction* (1970)	Both books revolutionized knowledge and attitudes about sex; *Response* showed that the female capacity for orgasm greatly exceeds that of most men, that Freud's theories of clitoral and vaginal orgasm needed revision, and that the capacity for meaningful sexual relationships continues into old age; *Dysfunction* stated that most sexual dysfunctions are amenable to some form of counseling; although that statement needed further verification, it gave hope to patients and sex counselors, and it stimulated the discipline of sex therapy
Organizational Psychiatry/ Diversity, Equity, Inclusion, and Justice	United States	Kenneth Clark becomes first African-American president of the APA in 1966.	
Margaret Mahler (1897–1985)	Central Europe until 1938, then United States	Mahler M, Pine F, Bergman A. *The Psychological Birth of the Human Infant: Symbiosis and Individuation*. Basic Books; 1975; *The Memoirs of Margaret S. Mahler*. Stepansky PE, ed. Free Press; 1988	Delineated the series of stages marking the infant's gradual intrapsychic separation from the mother and its understanding of itself as a distinct individual along with other equally distinct individuals
John Bowlby (1907–1990)	England	*Attachment* (1969), *Separation: Anxiety and Anger* (1973), *Loss: Sadness and Depression* (1980), *A Secure Base: Clinical Applications of Attachment Theory* (1988); *Holmes J. John Bowlby and Attachment Theory*. Routledge; 1993	Bowlby's attachment theory is largely based on the belief that a child's social and emotional development depends on the formation, maintenance, and renewal of attachment and affection as bonds between a child and parent (caregiver); deviant emotional and personality development is attributed to the rejection or disruption of ambivalent attachment bonds; loss, or threat of loss, of the attachment figure is viewed as a principal pathogenic agent; Bowlby furthermore believed that when the attachment behaviors of the child are nurtured by the caregiver, the child can develop a sense of security that then allows safe exploration of the world (environment), a positive sense of self, and good relations with others
Jacques Lacan (1901–1981), "the French Freud"	France	*The Language of the Self: The Function of Language in Psychoanalysis* (1968); *Turkle S. Psychoanalytic Politics: Freud's French Revolution*. Basic Books; 1978; Roudinesco E. Jacques Lacan & Co.: *A History of Psychoanalysis in France, 1925–1985*. University of Chicago Press; 1990	Emphasized language and the need to make contact with the prelanguage period in the unconscious and rejected the standard 50-minute analysis for sessions that were sometimes 10, 5, or even 3 minutes; founded a school of psychoanalysis, described as a return to Freud; at the time of his death, there were reportedly 5,000 Lacanian analysts in France; the most influential figure in French psychiatry; his ideas influenced literature, language, linguistics, economics, and mathematics; he was an integral part of the political left
Heinz Kohut (1913–1981)	Austria until 1940, then United States	*The Analysis of the Self* (1971); *The Restoration of the Self* (1977); The two analyses of Mr. Z. *Int J Psychoanal*. 1979;60:3; Baker H, Baker M. Heinz Kohut's self psychology: An overview. *Am J Psychiatry*. 1987;144:1; Strozier CS. Heinz Kohut: *The Making of a Psychoanalyst*. Farrar, Straus and Giroux; 2001	Originated the psychoanalytic school of self-psychology, which delineated a new group of developmental needs and three new views of transferences: Mirroring, idealizing, and alter ego
Jean Piaget (1896–1980)	Switzerland	Greenspan, Curry J. Piaget's approach to intellectual functioning. In: Kaplan HI, Sadock BJ, eds. *Comprehensive Textbook of Psychiatry*. 6th ed. Williams & Wilkins; 1995	Influenced by his observations of his three children, Piaget found four major stages in the formation of thought from infancy through adolescence, with each a necessary prerequisite for the one that follows: (1) *sensorimotor* (up to 2 years), child learns about space and permanent objects; (2) *preoperational* (2–7 years), verbal symbols are learned so words come to represent objects; (3) *concrete operations* (7–11 years), objects become classified according to similarities; (4) *formal operations* (11 years through end of adolescence), adult logical thinking is used more and more; although there have been criticisms and revisions of these four stages, they will (in the words of Greenspan and Curry) "serve as a basis for understanding social and emotional development and provide a framework for clinical and educational intervention"

Organizational Psychiatry/ Diversity, Equity, Inclusion, and Justice	United States	The Caucus of Gay, Lesbian, and Bisexual Members of the APA is founded in 1975.	The group quickly became an important advocacy group for LGBT mental health issues. In 1985 they changed their name to the Association of Gay and Lesbian Psychiatrists.
NAMI	United States	NAMI: *We Are Family*. Arlington, VA: NAMI; 1979; a 10-page brochure describing the work of NAMI; since then NAMI has published regular annual reports on its work	NAMI, founded in 1979 as an organization of patients with schizophrenia and their family members, has developed new approaches to working with families—counseling, individual family therapy, multifamily therapy groups, and psychoeducational programs—and is probably the most vigorous citizens' group in America that advocates to legislators and the public for the problems of persons with mental illness
Classification of mental disorders / Diversity, Equity, Inclusion, and Justice	United States	Transgender people are classified by the APA as having Gender Identity Disorder	
Sociobiologic psychiatry	United States, Holland	Van Praag H. Sociobiological psychiatry. *Compr Psychiatry*. 1981;22:441	An approach to the treatment of mental illnesses developed by the Dutch psychiatrist Herman van Praag; it analyzes the possibilities and limitations of pharmacotherapy and psychotherapy and their compatibility when used together in the treatment of psychiatric patients in various diagnostic categories
Roger Sperry (1913–1994)	United States	Some effects of disconnecting the cerebral hemispheres. *Science*. 1982;217:1223; Sperry RW, Levi-Montalcini R. In: Finger S, ed. *Minds Behind the Brain: A History of the Pioneers and Their Discoveries*. Oxford University Press; 2000	In 1981, Sperry shared the Nobel Prize in Physiology or Medicine for his work demonstrating that the left brain hemisphere contains the primary speech capacity, that the right hemisphere is involved with short-term memory, and that the two function independently when the connection between them is cut; this work (funded by grants from the NIMH) suggested that such states as autism and delusions sometimes may be caused by disturbances in the connections between the hemispheres
Brief psychotherapy	United States, England	Malan D. *A Study of Brief Psychotherapy*. Plenum Press; 1976; Mann J, Goldman R. *A Casebook in Time-Limited Psychotherapy*. McGraw-Hill; 1982; Davanloo H. *Short-Term Dynamic Psychotherapy*. Jason Aronson; 1980; Sifneos P. *Short-Term Dynamic Psychotherapy Evaluation and Technique*. Plenum Press; 1979; Crits-Cristoph P. The efficacy of brief dynamic psychotherapy: A meta-analysis. *Am J Psychiatry*. 1992; 149:151	Aims at producing insight and personality changes in a patient in a short, cost-limited time frame; it includes limiting time devoted to therapy, focusing on a particular problem, actively involving the therapist, engaging in anxiety-provoking confrontations, past–present link interpretations, and problem solving, recapitulating patient's resistances, emphasizing change and progress, and terminating early
Psychology of women	United States	Miller JB. *Towards a New Psychology of Women*. Beacon Press; 1976; Gilligan C. *In a Different Voice: Psychological Theory and Women's Development*. Harvard University Press; 1982; Levinson D, in collaboration with Levinson J. *The Seasons of a Woman's Life*. Knopf; 1996	Jean Baker Miller, Carol Gilligan, and Daniel Levinson offer different views on women's psychology and the female life cycle
Mental Health Policy		President Bill Clinton signs the Mental Health Parity Act	This act is later amended by President George W Bush in 2008 to close loopholes.
NARSAD	United States	NARSAD activities are reported in *Research* brochures and *Newsletters*	NARSAD was organized in 1986; in 1987, a funding program with 10 grants of $25,000 each was instituted; in 2003, NARSAD reported that in 15 years, it had awarded $144.4 million to fund 2,153 grants to 1,711 scientists at 312 universities and medical research institutions for research in schizophrenia and depression; in 2007 NARSAD announced that it had awarded 23 Distinguished Investigator grants and 222 Young Investigator grants; it has become the largest nongovernment, publicly funded organization that distributes funds for brain disorder research

Changes in the diagnosis and classification of homosexuality	United States	Bayer R. *Homosexuality and American Psychiatry: The Politics of Diagnosis*. Basic Books; 1981; DSM-III (1980); DSM-III-R (1987)	In 1973, in the light of new clinical information and under political pressure from the National Gay Task Force, the APA changed its diagnosis of homosexuality from a disease to a condition that can be considered a disease only if it is subjectively disturbing to the person; although some APA members protested the decision, it was upheld in a 1974 APA referendum; in the DSM-III, homosexuality was diagnosed as *ego-dystonic homosexuality*; in DSM-III-R, the reference to homosexuality was eliminated; some of the factors that influence a person to have a homosexual orientation are known (biology, family cultural environment, intrapsychic psychodynamics), but others remain unknown
Classification of mental disorders	United States	DSM-III (1980); DSM-III-R (1987); Wilson M. DSM-III and the transformation of American psychiatry: A history. *Am J Psychiatry*. 1993;150:399	The DSM-III-R reorganized the entire system of classifying diseases, leading to a more detailed, precise, and clear delineation of symptoms and a more medical and less psychoanalytic view of the symptoms; it was widely read and accepted in the United States and became the common language used by workers in psychiatry; the DSM-III-R was published because data from new studies were inconsistent with some of the previous diagnostic criteria and because of the need to review the criteria (along with systematic descriptions of diseases) for clarity and conceptual accuracy
Organizational Psychiatry	Europe	European Psychiatric Association founded in 1983	
Organizational Psychiatry/ Diversity, Equity, Inclusion, and Justice	United States	Carol Nadelson becomes first woman president of the APA in 1984.	
James Masterson (1926–), Otto Kernberg (1928–)	United States	Masterson J. *Psychotherapy of the Borderline Adult: A Developmental Approach*. Brunner/Mazel; 1976; *Narcissistic and Borderline Disorders: An Integrated Developmental*. Brunner/Mazel; 1981; Masterson J, Klein R, eds. *Psychotherapy of the Disorders of the Self: The Masterson Approach*. Brunner/Mazel; 1988; Kernberg O. *Borderline Conditions and Pathological Narcissism*. Jason Aronson; 1975; Kernberg O. *Severe Personality Disorders: Psychotherapeutic Strategies*. Yale University Press; 1984	Masterson and Kernberg developed two different psychoanalytic concepts (both emphasizing object relations) for understanding, diagnosing, and treating narcissistic and borderline personality disorders
Psychology and neurophysiology of dreams	United States	Hobson JA, McCarley RW. The brain as a dream state generator: An activation–synthesis hypothesis of one dream process. *Am J Psychiatry*. 1977;134: 1335; McCarley RW. Dreams: Disguise of forbidden wishes or transparent reflections of a distinct brain state? In: Bilder RM, Lefever H, eds. *Neuroscience of the Mind: On the Centennial of Freud's Project for a Scientific Psychology*. New York Academy of Sciences; 1998:116; Reiser MF. The dream in contemporary psychiatry. *Am J Psychiatry*. 2001;158:351	The Hobson–McCarley activation–synthesis hypothesis of dream formation, based on neurophysiologic research, postulates that dreams are caused by two reciprocally interacting groups of brainstem neurons; although this hypothesis at first tended to view dreams as products of brain physiology that lacked intrinsic psychological importance (and thus refuted Freud's psychoanalytic theory of dreams), this view has lately changed; Reiser suggested that new research has shown that the psychology of dreams is more complex than has been previously thought and postulated "a preliminary psychobiological concept of the dream process" in which "the mind exploits (for memory and cognitive functions) the special physiologic state of the activated dreaming brain"; Reiser emphasized that this concept is not a "final or complete understanding of the dream process," but that it may serve as a stimulus "for further research to both psychoanalysis and cognitive neuroscience"

Theories on the psychology of love	United States	Bergmann MS. *The Anatomy of Loving*. Columbia University Press; 1987; Sternberg RJ. *The Triangle of Love: Intimacy, Passion, Commitment*. Basic Books; 1987; Sternberg RJ, Barnes ML, eds. *The Psychology of Love*. Yale University Press; 1988; Caylin W, Person E, eds. Passionate *Attachments: Thinking about Love*. Free Press; 1988; Person E. *Dreams of Love and Fateful Encounters: The Power of Romantic Passion*. WW Norton; 1988	These books, which appeared within 1 year of one another, differed in their accounts of the nature of love; no one dominant theory emerged, yet each book offered new information and ideas on the phenomenology of love
Evaluations of psychotherapy	United States	Bruce R, Staples FR, Cristol AH, Yorkston NJ, Whipple KS. *Psychotherapy versus Behavior Therapy*. Harvard University Press; 1975; Elkin I, Shea MT, Watkins JT, Imber SD, Sotsky SM. National Institute of Mental Health Treatment of Depression Collaborative Research Program: General effectiveness of treatments. *Arch Gen Psychiatry*. 1989;48:971	Two methodologically sophisticated studies that concluded that groups of neurotic patients in psychotherapy showed a significant reduction in their symptoms when compared with control groups
Eric Kandel (1929–)	Austria, United States after 1939	Kandel E. Psychotherapy and the single synapse: The impact of psychiatric neurobiological research. *N Engl J Med*. 1979;301:1028; From metapsychology to molecular biology: Explorations into the nature of anxiety. *Am J Psychiatry*. 1983;140:1277; Genes, nerve cells, and the remembrance of things past. J Neuropsychiatry. 1989;1:103; Biology and the future of psychoanalysis: A new intellectual framework for psychiatry revisited. *Am J Psychiatry*. 1999;156:505; *In Search of Memory: The Emergence of a New Science of Mind*. WW Norton; 2006	Showed connections between psychiatry and neurobiology and research on the CNS of the snail *Aplysia*; developed an experimental system and set of conceptual approaches for studying the biologic basis of simple forms of learning and memory and demonstrated that "learning produces changes in neuronal architecture, changes that result from learned alterations in gene expression"; suggested that normal learning, learning of neurotic behavioral patterns, and unlearning of such detrimental behaviors through psychotherapeutic intervention might involve long-term functional and structural changes in the brain that result from altered gene expression; in his 1999 article, Kandel suggested ways of creating a discipline of neurobiology, cognitive psychology, and psychoanalysis that "would forge a new and deeper understanding of the mind" In 2000, the Nobel Prize for Physiology or Medicine was awarded to three men: Kandel for work in *Aplysia* (the second psychiatrist to receive the prize, after Wagner von Jauregg); Arvid Carlsson, a neuropsychopharmacologist at the University of Gothenburg in Sweden, known for his development of the dopamine hypothesis; and Paul Greengard, a neuroscientist at Rockefeller University in New York City, who studied how such neurotransmitters as dopamine communicate their signals at the cellular level. (Andreasen NC. Three living heroes of contemporary psychiatry. *Am J Psychiatry*. 2000;157:1911)
Aaron Beck (1921–)	United States	Beck A. *Cognitive Therapy and the Emotional Disorders*. International Universities Press; 1976; Beck A, Rush AJ, Shaw BF, Emery G. *Cognitive Therapy of Depression*. Guilford Press; 1979; Beck A, Emery G, Greenberg R. *Anxiety Disorders and Phobias: A Cognitive Perspective*. Basic Books; 1985; Beck A, Freeman A. *Cognitive Therapy of Personality Disorders*. Guilford Press; 1990; Weishaar M. Aaron T. Beck. *Key Figures in Counselling and Psychotherapy*. Sage; 1993; Barsky AJ, Ahern DK. Cognitive behavioral therapy for hypochondriasis. A randomized controlled trial. *JAMA*. 2004;291:1464	As formulated by Beck, cognitive therapy is a system of psychotherapy based on a theory of psychopathology and a set of therapeutic principles and techniques that emphasize the reorganization of a person's maladaptive processes of perceiving, thinking, and forming opinions; the study of Barsky and Ahern showed that cognitive-behavioral therapy in six 90-minute intervals "appears to have significant beneficial long-term effects on the symptoms of hypochondriasis." On November 16, 2007 Beck was one of five scientists chosen to receive the Lasker Award for his technique of cognitive therapy; the Award is considered the nation's most prestigious medical awards and carries a prize of $100,000. (*The New York Times*, November 17, 2007, Section N, p. 24)

Karl Menninger (1893–1990), William Menninger (1900–1966)	United States	Faulkner H, Pruitt V, eds. *The Selected Correspondence of Karl A. Menninger*. Yale University Press; 1988; Friedman LJ. *Menninger: The Family and the Clinic*. Knopf; 1990	The Menninger Clinic (founded in 1920 in Topeka, Kansas) became recognized for its innovative approaches to mental health, scientific excellence, and emphasis on public service; William Menninger introduced new, effective treatments for American psychiatric casualties in World War II; Karl Menninger applied psychoanalytic concepts to American psychiatry and wrote three popular and influential psychiatric-psychoanalytic books: *The Human Mind* (1930), *Man Against Himself* (1938), and *Love Against Hate* (1942); in June 2003, the Clinic moved from Topeka to Houston, Texas, where it became partners with Baylor College of Medicine and the Methodist Hospital
Frederick K. Goodwin (1936–), Kay Redfield Jamison (1946–)	United States	Goodwin FK, Jamison KR. *Manic-Depressive Illness*. Oxford University Press; 1990; 2nd ed., 2007	Offered a new diagnosis and classification of manic-depressive illness as a cluster of related illnesses, including bipolar disease, cyclothymia, and recurrent depressive disease; also offered the most comprehensive review of all information on the disease and all aspects of treatment, including medical (acute and prophylactic) and the role of psychotherapy
A memoir of depression	United States	Styron W. *Darkness Visible: A Memoir of Madness*. Random House; 1990	A national bestseller, described by the *Washington Post* as "a striking addition to the notable personal accounts of mental illness"; has been used by therapists as "an invaluable document" to help patients understand the symptoms of their depression. (*The New York Times*, November 12, 2006, Section 4, p. 11)
SSRIs	United States	"The Story of Prozac," Pharmaceutical Manufacturers Association; 1993; Grebb J. Serotonin-specific inhibitors. In: Kaplan HI, Sadock BJ, eds. *Comprehensive Textbook of Psychiatry*. 6th ed. Williams & Wilkins; 1995	SSRIs are antidepressants, generally as effective as previous antidepressants but with fewer adverse effects; the first SSRI, fluoxetine (Prozac), developed by Lilly in the 1970s, has become the most widely prescribed antidepressant in the United States; it was followed by sertraline (Zoloft), developed by Roerig in 1992, and paroxetine (Paxil), developed by SmithKline Beecham in 1993
Jerome Frank (1910–2005), E. Fuller Torrey (1937–)	United States	Frank J. *Persuasion and Healing: A Comparative Study of Psychotherapy*. Johns Hopkins University Press; 1961; 2nd rev. ed., 1973; Frank J, Frank JB. *Persuasion and Healing: A Comparative Study of Psychotherapy*. 3rd rev. ed. Johns Hopkins University Press; 1991; Torrey EF. *The Mind Game: Witchdoctors and Psychiatrists*. Emerson Hall; 1972; Torrey EF: *Witchdoctors and Psychiatrists: The Common Roots of Psychotherapy and its Future*. Harper & Row; 1986 (a revised edition of *The Mind Game*)	These books offered perspectives on the practices of contemporary American psychotherapy and psychotherapists by delineating how psychic changes are effected in a wide range of therapist–patient interactions, including miracle cures, faith healing, Communist thought control, the so-called placebo effect in medicine, special types of individual and group psychotherapies, and the work of traditional healers in third-world countries and among Mexican and Puerto Rican Americans and Navaho
Neuroimaging	United States	Kenneth Kwong publishes his pioneering work in functional brain imaging in 1992	
Psychiatric epidemiology	United States	Robins LN, Regier DA, eds. *Psychiatric Disorders in America: The Epidemiologic Catchment Area Study*. Free Press; 1991	This NIMH Epidemiologic Catchment Area study, the largest and most sophisticated study of psychiatric epidemiology ever undertaken in the United States, showed that more than 30% of individuals have at least one psychiatric disorder (and many have more than one); that alcoholism and phobic disorder are the most common illnesses, followed by depression; that the uneducated, unmarried, and divorced are more vulnerable; that, more important than race or economic status as a predictor of most illness, the young are more vulnerable than their elders; the study permitted follow-up and evaluation of changes (both overall and in specific areas) to show how particular services are used or not used; it thus continues to provide data for an ongoing discussion of mental health needs and future psychiatric research projects

Forensic psychiatry	United States	Bursztajn H, Scherr A, Brodsky A. The rebirth of forensic psychiatry in light of recent historical trends in criminal responsibility. *Psychiatr Clin North Am*. 1994;1(3):611; Prentice S. A history of subspecialization in forensic psychiatry. *Bull Am Acad Psychiatry Law*. 1995;23(2):195	Changing concepts of criminal responsibility in mid-20th century America, and interactions between the American Academy of Forensic Sciences and the American Academy of Psychiatry and the Law, resulted in forensic psychiatry's becoming officially recognized as a subspecialty by the American Board of Medical Specialties on September 17, 1992, under the designation of "Added Qualification in Forensic Psychiatry"
Epidemic of AIDS and of persons infected with HIV (1981–)	Worldwide	Grmek M. *History of AIDS: Emergence and Origin of a Modern Pandemic*. Princeton University Press; 1990; Berridge V, Strong P, eds. *AIDS and Contemporary History*. Cambridge University Press; 1993; Feldman D, Miller J, eds. *The AIDS Crisis: A Documentary History*. Greenwood Press; 1998; Bayer R, Oppenheimer G, eds. *AIDS Doctors: Voices from the Epidemic*. Oxford University Press; 2000; Treisman G, Angelino F. *The Psychiatry of AIDS: A Guide to Diagnosis and Treatment*. Johns Hopkins University Press; 2004; Mayer K, Pizer H, eds. *The AIDS Pandemic: Impact on Science and Society*. Elsevier Academic Press; 2005	Psychiatrists are called on to manage individuals who are at high risk for HIV infection or who are HIV infected and to treat the psychiatric disorders that result from or are comorbid with HIV infection; these disorders include dementia, delirium, anxiety, and disorders of cognition, adjustment, mood, and sleep; because AIDS is largely caused by sexual contact and IV drug use, psychiatrists and mental health professionals need to teach the techniques of safe sex and safe drug use and work with addicts to withdraw from drug; the global incidence of AIDS is steadily increasing
Classification of mental disorders	United States	*American Psychiatric Association: Diagnostic and Statistical Manual of Mental Disorders*. 4th ed. Text rev. American Psychiatric Association; 2000 (DSM-IV-TR)	The DSM-IV, probably the most ambitious undertaking in the history of American psychiatric nosography, was based on 6 years of collecting and analyzing relevant information and making field tests of proposed changes in diagnosis; it continued the atheoretical approach to causes, made fewer diagnostic changes than the DSM-III, systematically described each disorder in terms of its associated features, and replaced the DSM-III-R as the diagnostic text used by workers in psychiatry; the DSM-IV-TR contained updated information about the associated features, prevalence, course, and familial pattern of some of the mental disorders that had been described in the DSM-IV; it also gave more comprehensive diagnostic criteria for personality change due to a general medical condition, paraphilias, and tic disorders than those given in the DSM-IV
Clozapine, risperidone, and olanzapine in the treatment of schizophrenia	United States, Canada, Europe, England, South America, South Africa	Kane J, Honigfield G, Singer J, Meltzer H, and the Clozaril Collaborative Study Group: Clozapine for the treatment-resistant schizophrenic. A double-blind comparison with chlorpromazine. *Arch Gen Psychiatry*. 1988;45:789; Kane J, Marder SR. Clozapine benefits and risks. *Schizophren Bull*. 1994;20:23; Ayd FJ Jr. Risperidone (Risperdal): A unique antipsychotic. *Int Drug Ther Newslett*. 1994;29:5; Marder SR, Meibach RC. Risperidone in the treatment of schizophrenia. *Am J Psychiatry*. 1994;151:825; Kane J. Risperidone. *Am J Psychiatry*. 1994;151:802; Beasley C, Tollefson G, Tran P, Satterlee W, Sanger T. Olanzapine versus placebo and haloperidol acute phase results of the North American double-blind olanzapine trial. *Neuropsychopharmacology*. 1996;14:111; Tollefson G, Kuntz A. Review of recent clinical studies with olanzapine. *Br J Psychiatry*. 1999;37:30; Volavka J, Czobor P, Sheitman B, Lindenmayer JP, Citrome L. Clozapine, olanzapine, risperidone, and haloperidol in the treatment of patients with chronic schizophrenia and schizoaffective disorder. *Am J Psychiatry*. 2002;159:255; Grilly J. The history of clozapine and its emergence in the U.S. market: A review and analysis. *Hist Psychiatry*. 2007;18:39	Clozapine and risperidone have been used successfully since 1989 and 1994 to treat both positive and negative schizophrenic symptoms that have been resistant to other treatments; these drugs each offer the possibility for real and continued improvement of individuals who are persistently psychotic; olanzapine has been in use since September 1996 and is effective in treating positive and negative schizophrenic symptoms; the 2002 study by Volavka et al. on 157 hospital in-patients who had a diagnosis of chronic schizophrenia or schizoaffective disorder showed that clozapine, risperidone, and olanzapine (but not haloperidol) resulted in statistically significant improvements in the positive and negative symptoms of hospital patients: "The overall pattern of results suggests that clozapine and olanzapine have similar general antipsychotic efficacy and that risperidone may be somewhat less effective. Clozapine was the most effective in treatment for negative symptoms. However, the differences were small."

Publications in psychohistory and psychobiography	United States, England	Lawton H. *The Psychohistorian's Handbook*. Psychohistory Press; 1988; Elovitz P, ed. Clio's Psyche. Understanding the "Why" of Culture, Current Events, History, and Society (1994) (a quarterly periodical published by the Psychohistory Forum, 627 Dakota Trail, Franklin Lakes, NJ 07417); Sabbadini A, ed. Psychoanalysis and History. Vol. 1, No. 1. Artesian Books; 1998–1999 (since its first issue, this *History* has appeared at regular intervals of twice a year; since 2005 edited by John Forrester, and since 2007 published by Edinburgh University Press); Szaluta J. *Psychohistory: Theory and Practice*. Peter Lang; 1999; Elovitz P. Psychoanalytic scholarship on American Presidents. *Annu Psychoanal*. 2003;31:135; Schultz WT, ed. *Handbook of Psychohistory*. Oxford University Press; 2005	Lawton defined *psychohistory* "as the interdisciplinary study of why man has acted as he has in history, prominently utilizing psychoanalytic principles" (no uniformly accepted definition exists); examined different psychohistorical writings, concepts, and methods of doing interdisciplinary research (most of which date from the appearance of Erikson's *Young Man Luther* in 1958); and called attention to the two best-established journals in the field, started in the 1970s: the *Psychohistory Review* (stopped publication in 1999) and the *Journal of Psychohistory; Clio's Psyche* has short, concise studies by various authors on greatly varied subjects (including the personalities of famous individuals, presidential character, nationalism, ethnic conflicts and the Holocaust, AIDS, movies, psychological issues, psychoeconomics, and the environment); many studies aim to combine primary research with psychological insights; notable interviews with distinguished psychohistorians (in his interview with *Clio*, psychohistorian Peter Loewenberg commented, "I'd like to get away from the idea of applying psychoanalysis to history because I think the integration of psychodynamic perceptions with historical conceptualization should take place at the moment that the historian contacts the data or the archives. Both history and psychoanalysis are fundamentally historical enterprises—they're models of explanation.") *Psychoanalysis and History* has two stated aims: (1) "historiographic studies of the psychoanalytic movement itself, as well as biographical research on aspects of the lives and works of prominent psychoanalysts. Only one century old, psychoanalysis has an already rich and articulated history, having undergone complex external and internal vicissitudes and having developed its identity in most diverse ways in different geographical regions. We intend … to present as yet unpublished documents … which will throw new light on a number of important aspects of our discipline" and (2) "We shall also attempt to apply psychoanalytic ideas—for instance the concept of unconscious processes, of developmental stages, or of relevant defence mechanisms such as repression, splitting, projective identification and 'deferred action' (Nachtraglichkeit)—to the interpretation of historical events" Szaluta's book was the first text to present both the theory and practice of psychohistory; the contributions of Freud and post-Freudians were delineated, the pros and cons of psychohistory examined, and major works of psychohistory discussed; Szaluta emphasized how psychohistory differs from traditional history and how it can be insightful in the study of the individual, the family, and the group Elovitz discussed how, in almost three decades of research on presidential psychobiography, he was influenced by psychoanalysis to develop a method of "disciplined subjectivity" in which he applied the "nonjudgmental manner of the clinician … to the politician"; he studied his subject's childhood, personality, family background, life crises, defense mechanisms, and patterns of success and failure; throughout the entire process, he carefully monitored countertransference feelings; as a result of following this method, he claimed to understand both the pressures of office and the personalities of presidents and to have insights into "understanding the contradictory desires, the ambivalence, of both the leader and the led" A *Handbook of Psychohistory* offers articles on psychohistory and psychobiography that show a variety of different psychological approaches

Paul Wender (1934–)	United States	*Attention-Deficit Hyperactivity Disorder in Adults*. Oxford University Press; 1998	As a result of his 25 years of studying ADHD in adults, Wender gave new evidence suggesting that ADHD is genetically transmitted and that approximately one-third of children with ADHD reach adulthood with persisting symptoms of the disorder; he also reviewed what was known about ADHD's symptoms, its life course, and the value of treatments with various drugs
Computers and the Internet	United States	The APA has published two books on the use of computers in psychiatry: *Lieff J. Computer Applications in Psychiatry*. American Psychiatric Publishing; 1987; and Chan CH, Luo JS, Kennedy RS. *Concise Guide to Computers in Clinical Psychiatry*. American Psychiatric Publishing; 2002; Miller MJ. Computer-based testing of the psychiatric patient. In: Sadock BJ, Sadock VA. *Comprehensive Textbook of Psychiatry*. 7th ed. Lippincott Williams & Wilkins; 2000	Computers have been applied to practically every area of psychiatry, including recording patient symptoms, facilitating the transfer of records, tracking patients in the community, and establishing databases; they have been used by insurance companies and managed care companies for accounting and monitoring patient care, and, since the 1970s, they have been used with increasing frequency in giving patients psychological tests
		Two articles about the Internet are Alessi NE. The Internet and the future of psychiatry. *Am J Psychiatry*. 1996;153:861; and Rajendran PR. The Internet: Ushering in a new era of medicine. *JAMA*. 2001;285:804	The Internet is a computer communication network that transmits information quickly and easily on a global scale, facilitating contacts between different psychiatrists, and between psychiatrists and patients, and enabling patients to obtain rapid information on the professional qualifications of the psychiatrist who is treating them and the psychiatric medications the psychiatrist has prescribed for them Although the Internet has given new information to persons who previously had not been able to obtain this information, it is information that sometimes needs to be used with caution because it can be the result of covert advertising by individuals or companies and has not been scientifically evaluated
Discoveries of genetic variations as causes of mental illnesses	United States, Canada, England, Europe, Australia	Oberlé I, Rousseau F, Heitz D, Kretz C, Davys D. Instability of a 550–base pair DNA segment in fragile X syndrome. *Science*. 1991;252:1097; Yu S, Pritchard M, Kremer E, Lynch M, Nancarrow J. Fragile X genotype characterized by an unstable region of DNA. *Science*. 1991;252:1179; Ying-Hui Fu, Kuhl DPA, Pizzuti A, Pieretti M, Sutcliffe JS. Variation of the CGG repeat at the fragile X site results in genetic instability: Resolution of the Sherman paradox. *Cell*. 1991;67:1047; Schellenberg GD, Bird TD, Wijsman EM, Orr T, Anderson L. Genetic linkage of evidence for a familial Alzheimer's disease locus on chromosome 14. *Science*. 1992;258:668; Mullen M, Houlden H, Windelspecht M, Fidani L, Lombardi C. A locus for familial early-onset of Alzheimer's disease on the long arm of chromosome 14, proximal to the α-1-antichymotrypsin gene. *Nat Genet*. 1992;2:340; The Huntington's Disease Collaborative Research Group: A novel gene containing a trinucleotide repeat that is expanded and unstable on Huntington's disease chromosome. *Cell*. 1993;72:971; Amir RE, Van den Veyver IB, Wan M, Tran CQ, Franke U. Rett syndrome is caused by mutations in X-linked MECP2, encoding methyl-CpG-binding protein 2. *Nat Genet*. 1999;23:185	During 1991–1993, genetic variations were identified as causes for the fragile X syndrome, a common cause of inherited mental retardation; familial early onset of Alzheimer disease; and Huntington disease; in 1999, it was discovered that the MECP2 gene causes Rett syndrome, a pervasive developmental disorder included in the DSM-IV classification

		Hyman S, Moldin S. Genetic science and depression: Implications for research and treatment. In: Weissman MM, ed. *Treatment of Depression: Bridging the 21st Century*. American Psychiatric Association; 2001:98; Andreasen NC. Schizophrenia. Chapter 8. In: *Brave New Brain: Conquering Mental Illness in the Era of the Genome*. Oxford University Press; 2001:199	The 2001 article by Hyman and Moldin stated that, although previous studies had shown that heredity plays a role in the transmission of depression, "a single major gene is an unlikely contributor to etiology; rather, multiple genes of small effect contribute with nongenetic factors in producing vulnerability to the illness"; in the same year, Andreasen observed, "Most experts now think that schizophrenia is clearly multifactorial, involving multiple genes, and possibly even different genes in different individuals, as well as many nongenetic or environmental influences. The fact that multiple genes are probably involved is the main reason why the various reports that 'the schizophrenia gene has been found on chromosome 5' (or 11 or 22 or elsewhere) have not been consistently repeated"
Three books on psychotherapy	United States	Jackson SW. *Care of the Psyche: A History of Psychological Healing*. Yale University Press; 1999; Sabo AN, Havens L, eds. *The Real World Guide to Psychotherapy Practice*. Harvard University Press; 2000; Hersen M, Sledge WH, eds. *Encyclopedia of Psychotherapy*. 2 Vols. Academic Press; 2002	Jackson's *History* is notable for its delineation of the roles of healer and sufferer throughout history; the essays by Sabo, Havens, and others suggest how, through forming relationships with patients, it is possible to do some effective psychotherapy and to counter the constraints of managed care; the *Encyclopedia* gives concise articles, written by experts, on the major psychotherapies that are now in use, along with studies of the efficacy of each of these therapies
Education of psychiatrists	United States	Luhrmann TM. *Of Two Minds: The Growing Disorder in American Psychiatry*. Knopf; 2000	Depicts contemporary American psychiatry as divided between two views of mental illness: A biomedical model, consisting of symptoms treated by psychopharmacology, and a psychodynamic model, consisting of emotional conflicts, treated by psychotherapy; although Luhrmann states that the use of both models together is necessary in treating patients, she observes that "a combination of socio-economic forces [managed care] and ideology is driving psychotherapy out of psychiatry"; she also observes that this would be bad for psychiatrists and patients and encourages "a way of thinking about mental illness that can strip humanity from its sufferers"
Theory and treatment of depression	United States, England, Switzerland	In a March 1999 New York City meeting of the American Psychopathological Association, leading clinical scientists gave papers on the topic Treatment of Depression, all of which were published as in Weissman MM, ed. *Treatment of Depression: Bridging the 21st Century*. American Psychiatric Association; 2001	The papers ranged widely in discussing different aspects of depression; Charles Nemeroff and Michael Owens, in "Contribution of modern neuroscience to developing new treatments for psychiatric disorders," reviewed the evidence that CRF is hypersecreted in depressed patients, that "untoward early life experience is associated with a persistent CRF gene expression and CRF neuronal activity, which may underlie the vulnerability of individuals exposed to child abuse or neglect to develop depression in adulthood," and that the recent use of a CRF antagonist for the treatment of major depression has been successful; Steven Hyman and Steven Moldin, in "Genetic science and depression: Implications for research and treatment," delineated the growth in knowledge from the Human Genome Project, the interactions of different genomes with their environments and protein products, *proteomics*, and then suggested that "the greatest benefit from genetic research is likely to come in the development of platforms for drug discovery and for understanding the genetic contributions to drug action"

Telegram: @medical_k

www.konkur.in

			Other papers gave overviews of various treatments; in the United States, there are 20 FDA-approved antidepressants, which in general are "moderately effective," although none of them cures depression, and "a significant number of people either do not respond or respond only partially"; there are two new physical therapies—transcranial magnetic stimulation and vagus nerve stimulation—that remain to be evaluated; there is evidence that cognitive or behavioral therapy each is effective in the treatment of clinical depression; in an epilogue, Weissman observed, "treatment for depression is more targeted, faster, and with fewer side effects and is aimed at the underlying pathophysiology of depression"
Neuroimaging	United States	Andreasen NC. Mapping the mind. In: *Brave New Brain: Conquering Mental Illness in the Era of the Genome*. Oxford University Press; 2001:130; Morihisa JM, ed. Advances in Brain Imaging. American Psychiatric Association, 2001	Beginning in the 1970s and 1980s, techniques of CT and MRI showed how the brain was physically diminished in the dementias and other organic illnesses and how, in some cases of schizophrenia, the ventricles were enlarged; after this discovery, what were known as "functional techniques of neuroimaging"—including functional MRI, single photon emission computed tomography, and PET—were applied to studying changes in brain activity (blood flow) in mental illness; although Andreasen stated that most of these techniques are still research tools, she also observed that in some illnesses "PET permits us to study the relationship between drug dose and clinical response based on a measurement of the levels and activity in the brain"
The effects of traumatic events on individuals	United States, England, France, Germany, and Italy	Micale MS, Lerner P, eds. *Traumatic Pasts, Psychiatry, and Trauma in the Modern Age, 1870–1930*. Cambridge University Press; 2001	A collection of essays by scholars from different disciplines, describing how individuals in several countries suffered medical and psychological disturbances from the effects of railroad accidents, accidents at work, remembering traumatic events in their lives, and the aftermath of shell shock in World War I; in their essay "Trauma, psychiatry, and history," Lerner and Micale commented that there is no "single, uniform, transhistorically valid concept of psychological trauma," and that although it is "impossible to write a single, unilinear history of trauma," it is possible to write case histories of how individuals experienced trauma and to collate these experiences with the ideas about the nature of trauma that were held by scientists and social groups and that were dominant in the cultures in particular moments in the past
Diagnosis and treatment of borderline personality disorder	United States	Gunderson JG. *Borderline Personality Disorder: A Clinical Guide*. American Psychiatric Association; 2001; American Psychiatric Association. *Practice Guideline for the Treatment of Patients with Borderline Personality Disorder*. American Psychiatric Association; 2001; Oldham JM. A 44-year-old woman with borderline personality disorder. *JAMA*. 2002;287:1031	Gunderson' *Guide* and the APA's *Practice Guideline* recommend combinations of long-term psychotherapy (often consisting of cognitive therapy or psychodynamic psychotherapy) and medications that are targeted for specific symptoms, and include low-dose antipsychotics and SSRIs; Oldham observed that, after this treatment, "over time, most patients with borderline personality disorder show substantial improvement"
September 11, 2001, terrorist attacks on the World Trade Center and the Pentagon	United States	Kleinfield NR, Connelly M: 9/11 still strains New York psyche. Poll finds widespread unease and lingering fear of terror. *The New York Times*, September 8, 2003, Section A, pp. A1–A2; Sheehy G: Middletown America. *One Town's Passage from Trauma to Hope*. Random House; 2003; Cancelmo JA, Tylim I, Hoffenberg J, eds. *Terrorism and the Psychoanalytic Space: International Perspectives from Ground Zero*. Pace University Press; 2003	The 9/11 terrorist attacks were notable for their amalgam of violence, loss, and death and for the great variability of the mental and physical reactions that followed from these attacks; whereas some individuals have recovered and formed what Gail Sheehy describes as a "new life," others have suffered from persisting episodes of PTSD, anxiety, depression, physical symptoms, and fears that there will be new terror attacks; 5 years after the attack two-thirds of New Yorkers said they were still "very concerned" about another attack on their city (*The New York Times*, September 7, 2006)

www.konkur.in

Overviews of psychoanalysis	United States	Erwin E, ed. *The Freud Encyclopedia: Theory, Therapy, and Culture*. Routledge; 2002; Zaretsky E. *Secrets of the Soul: A Social and Cultural History of Psychoanalysis*. Knopf; 2004	The *Encyclopedia* consists of more than 200 entries by Freud scholars, which include biographical sketches of Freud (with an entry on his family) and of individuals who contributed to the development of psychoanalysis; entries on each of Freud's famous case histories; evaluations of Freud's theories of anxiety and defense, drives, the unconscious and repression, neuroses, and narcissism; the influence of psychoanalysis on such humanistic disciplines as anthropology and cultural studies, history and biography, literary criticism, film studies, and philosophy, as well as on biology and neurobiology; and the history and current state of psychoanalysis in various countries in Europe, the Americas, and Africa, as well as in Great Britain, Australia, Japan, Korea, China, India, and the Philippines *Secrets of the Soul* gives kaleidoscopic overviews of how Freud's ideas were influenced by the social, political, and cultural climates in which these ideas originated; Zaretsky argues that "the idea of a *personal* unconscious was new" and "gave expression to possibilities of individuality, authenticity, and freedom that had only recently emerged" and that then played an important role in "the modernism of the 1920s, the English and American welfare states of the 1940s and 1950s, the radical upheavals of the 1960s, and the feminist and gay-liberation movements of the 1970s"; at the same time, in ways that were complex and paradoxical, psychoanalysis became "a fount of antipolitical, antifeminist, and homophobic prejudice" and led to the creation of other psychotherapies and movements that in many cases replaced it; Zaretsky's book is a pioneering attempt to delineate the historical impact of psychoanalysis
Psychosomatic medicine	United States	Blumenfield M, Strain J, eds. *Psychosomatic Medicine*. Lippincott Williams & Wilkins; 2006	In 2003, the American Board of Psychiatry and Neurology granted a psychiatric subspecialty status to psychosomatic medicine, and in 2005, the first board examination in psychosomatic medicine was held; the book edited by Blumenfield and Strain consists of a collection of articles giving comprehensive accounts of psychosomatic symptoms in medical, psychiatric, and neurologic illnesses and how these symptoms can be treated
Confinement of the mentally ill in asylums	South Africa, Switzerland, France, Canada, Australia, Germany, United States, Japan, Argentina, Mexico, India, Nigeria, Ireland, and England	Porter R, Wright D, eds. *The Confinement of the Insane. International Perspectives, 1800–1965*. Cambridge University Press; 2003	This volume brings together 14 original research papers by different scholars, each of whom examines the social forces that influenced the confinement of the insane in asylums in different countries during different periods of time in the 19th and 20th centuries; summing up the contents of the papers, Porter concluded that the history of the growth of asylums "proves more complex than it might seem," revealing that "the asylum was neither just a site for care and cure, nor just a convenient place for locking up inconvenient people ('custodialism'). It was many things all at once. And far from being a weapon securely under the control of the [psychiatric] profession, or the state, it was a contested site, subject to continual negotiations among different parties, including families and the patients themselves"

Treatment of schizophrenia	United States	American Psychiatric Association: *Practice Guideline for the Treatment of Patients with Schizophrenia*. 2nd ed. American Psychiatric Association; 2004	Recommendations that are intended to help psychiatrists in assessing and treating adult patients with schizophrenia in their acute phase, treatment stabilization phase, and stable phase; each recommendation receives one of three categories of endorsement: Recommended with substantial confidence, recommended with moderate confidence, and may be recommended on the basis of individual circumstances; although the *Practice Guideline* is based on synthesis of "current scientific knowledge and rational clinical practice," it is emphasized that it is only a guideline, that it should not be construed to serve as a standard of medical care, and that "the ultimate judgment regarding a particular clinical procedure or treatment plan must be made by the psychiatrist in light of the clinical data presented by the patient and the diagnosis and treatment options available"
College Mental Health	United States	Kadison R, Geronimo I. *College of the Overwhelmed: The Campus Mental Health Crisis and What to Do about It*. Jossey-Bass; 2004	Delineates the mental pressures faced by college students as they confront academic requirements, explore sexuality, and form new interpersonal relationships; as a result of these pressures, "since 1988, the likelihood of a college student suffering depression has doubled, suicidal ideation has tripled and sexual assaults have quadrupled"; on the second half of the book, in a chapter entitled "For students only," Kadison and Geronimo offer proactive ways for students to maintain mental balance and how to seek help if things go wrong
A suppressed psychiatric scandal	United States	Scull A. *Madhouse: A Tragic Tale of Megalomania, and Modern Medicine*. Yale University Press; 2005	The madhouse Scull writes about was the Trenton State Hospital in New Jersey from 1907 to 1930, when Henry Cotton was its Superintendent; believing that infections of various body parts were a cause of psychiatric illness, Cotton treated psychiatric patients by surgical extirpation of these parts, which were mainly teeth and tonsils, but which also included stomachs, gallbladders, colons, testicles, and ovaries; when Adolf Meyer had the young psychiatrist Dr. Phyllis Greenacre investigate Cotton's treatments, Greenacre reported that these treatments resulted in deaths, disabilities, and questionable improvement of psychiatric symptoms; however, Meyer suppressed her report; Cotton was demoted from Superintendent to Director of Research; a public scandal was thus averted, and knowledge of Cotton's operations remained unknown for many years until Scull, after doing research based on documents and the recollections of several individuals, uncovered what had been unknown and published his book
Use of amphetamines as antidepressant drugs	United States	Rasmussen N. Making the first antidepressant: Amphetamine in American medicine, 1929–1950. *J Hist Med Allied Sci*. 2006;61:288	Shows how during the 1940s and 1950s amphetamine was a very commonly prescribed remedy for depression and related neurotic conditions, used by both general practitioners and psychiatrists; in the 1960s, although amphetamine was used in a variety of conditions, it largely stopped being used in most psychiatric cases, being replaced by the minor tranquilizers and the MAOI and tricyclic antidepressants
Recollections of treating schizophrenia	United Sates	Seeman M. Forty-five years of schizophrenia: Personal reflections. *Hist Psychiatry*. 2006;17:363	Seeman recollected that, in the 45 years since she has been treating schizophrenia, "although there have been many advances over this period, understanding of schizophrenia continues to be elusive, and treatments remain imperfect. Therefore, as perspectives shift and the ground moves beneath us, the psychiatric profession need to anchor itself firmly in the stories our [schizophrenic] patients tell us." Whether these stories "be of symptoms, of loss or of survival."

Mental health policy	United States	Frank R, Glide S. *Better But Not Well: Mental Health Policy in the United States Since 1950*. Johns Hopkins University Press; 2006	The mentally ill have improved due to the development of better-tolerated medications (selective serotonin reuptake inhibitors compared with tricyclic antidepressants) and the development of policies such as Medicare, Medicaid, Social Security Disability Insurance, and the expansion of private health insurance; however, the majority of the mentally ill are impoverished, and there has been no increase in their rates of employment; in addition, during the last 50 years their rates of homelessness have more than doubled, and incarcerations have gone up fivefold
George Mora (1923–2006), and his work in the history of psychiatry	Italy and after 1953 the United States	Works on the history of Italian psychiatry, a wide range of medical and psychiatric topics, a translation of Johann Weyer's *De praestigiis daemonum* (1991), and with Jeanne Brand, *Psychiatry and Its History: Methodological Problems in Research* (1970)	For a generation Mora was the foremost American authority on the history of psychiatry, as well as the author of the sections of the history of psychiatry for the first four editions of the *Comprehensive Textbook of Psychiatry*
Mood disorders	United States	In 2006–2007 two textbooks on mood disorders were published: Stein D, Kupfer D, Schatzberg A, eds. *The American Psychiatric Publishing textbook of Mood Disorders*. American Psychiatric Publishing; 2006; Goodwin FK, Jamison KR. *Manic-Depressive Illness: Bipolar Disorders and Recurrent Depression*. 2nd ed. Oxford University Press; 2007 (1st ed., 1990)	Each of these books gave detailed information on the latest knowledge of the causes, symptoms, and treatments of mood disorders
Albert Ellis (1913–2007)	United States	Ellis published 75 books, including *Overcoming Procrastination, How to Live With a Neurotic, Sex Without Guilt*, and *A Guide to Rational Living*	By late 1953, Ellis had begun developing Rational Emotive Behavior Therapy (REBT), a mode of therapy that aimed at helping individuals make psychological changes by teaching them to challenge their self-defeating thoughts; in 1960, he founded the Albert Ellis Institute to promulgate his work; he continued the shift of psychotherapy from psychoanalysts and from physicians to clinical psychologists and psychiatric social workers, which had been begun by Carl Rogers; in 2003, the American Psychological Association named him the second most influential psychologist of the 20th century, second only to Rogers
Diversity, Equity, Inclusion, and Justice	United States	American Psychiatric Association issues their official position supporting the care and rights of transgender and gender nonconforming individuals.	
Mental Health Policy	United States	Mental Health Parity and Addiction Equity Act of 2008. "Fact Sheet": The Mental Health Parity and Addiction Equity Act of 2008 (MHPAEA). Accessed November 19, 2015. Available at http://www.dol.gov/ebsa/newsroom/fsmhpaea.htm	Enacted in 2008 as part of the Affordable Care Act to address loopholes created by the initial Mental Health Parity Act of 1996. The act (1) includes mental health and substance use disorder benefits in the *Essential Health Benefits;* (2) applies federal parity protections to mental health and substance use disorder benefits in the individual and small group markets; and (3) provides more Americans with access to quality health care that includes coverage for mental health and substance use disorder services.
Organizational Psychiatry/ Diversity, Equity, Inclusion, and Justice	United States	Saul Levin named CEO of the APA in 2013.	This makes Dr. Levin the first openly gay person to lead a national medical specialty society in the United States.

Telegram: @medical_k

www.konkur.in

Classification of Mental Disorders	United States	American Psychiatric Association. *Diagnostic and Statistical Manual of Mental Disorders.* 5th ed. American Psychiatric Association; 2013	In 2013, this revision to the DSM-IV was published, with several important changes: Aspergers and Autism disorders were subsumed under the term *autism spectrum disorders:* criteria were added to ADHD to facilitate application across the lifespan; symptoms must now be present before age 12 (vs. age 7 in DSM-IV); subtype specifiers of schizophrenia were eliminated due to their limited diagnostic stability, low reliability, and poor validity. In bipolar disorder, a "with mixed features" specifier has been added; Addition of disruptive mood dysregulation disorder and premenstrual dysphoric disorder; bereavement exclusion now omitted from criterion of MDD; OCD and related disorders are a new diagnostic category and include hoarding disorder excoriation (skin-picking) disorder; adjustments made to criterion for trauma and stress-related disorders; creation of gender dysphoria as a new diagnostic class. Substance disorders expanded to include gambling disorder.
Mentally ill and gun violence	United States	Metzl, Johnathan M., and Kenneth T. Machleish. "Mental Illness, Mass Shootings, and the Politics of American Firearms." *Am J Public Health.* 2015: 240–249	There is increasing focus on mental illness and gun violence in the wake of several mass shootings, which reflects decades-long history of more general debates in psychiatry about guns, violence, and mental competence. Social and political rhetoric following these violent events strengthen implications that mental illness caused these events or earlier detection of these problems might have prevented them. Many states reactively enacted legislation requiring mental health clinicians to report "dangerous patients" to local officials as a way to prevent these people from obtaining firearms. Many argue that the focus should be on prevention efforts that will have a boarder impact on communities such as reexamination of gun laws and improving mental health resources.
Changes in marijuana legislation	United States (23 states)	Wilkinson, Sauel T, Stephanie Yarnell, Rajiv Radhakrishnan, Samuel A. Ball, and Deepak Cyril D'souza. "Marijuana Legalization: Impact on Pyschicians and Public Health." *Ann Rev Med.* 2014	Between 1996 and 2015, 23 states passed laws legalizing marijuana use for medical purposes after numerous studies revealed its therapeutic potential for multiple medical conditions including epilepsy, cachexia, and chronic pain. Several states have legalized small amount of marijuana for recreational use reflecting a growing shift in public opinion regarding the safety or marijuana. Marijuana use and sale remains illegal under federal law and it is still listed as schedule I substance. Many states are calling for federal decriminalization of marijuana but the debate rages on given remaining concerns about legalization and public health effects. Despite efforts to reschedule marijuana, it continues to be classified as a schedule I substance.
United States Drug Enforcement Agency	United States	Wing N. (2015, March 18). DEA Approves Study of Psychedelic Drug MDMA In Treatment of Seriously Ill Patients. Retrieved November 17, 2015, from http://www.huffingtonpost.com/2015/03/18/deadmda-study_n_6868972.htm	MDMA was classified as a schedule I substance in 1985. In the years since, recent studies have shown that the drug can be effective for mental disorders. DEA approved study of MDMA in the treatment of anxiety in people with life-threatening illness. This comes after studies showing that MDMA can be helpful for disorders like PTSD in a supervised treatment setting.
Physician-assisted suicide	United States	Dyer, Owen, Caroline White, and Aser Garcia Rada. "Assisted Dying: Law and Practice around the World." Bmj (2015): Payne, Kate. "Consider Assisted Suicide." Tennessee Nurse 78.3 (2015): n. pag. Web 17 November 2015 Kopelman, Loretta M. Physician- assisted Suicide: What Are the Issues? Kluwer Academic Publishers, 2001	Medical professional codes have long prohibited physicians involvement in assisting a patient's suicide. However, despite ethical and legal prohibitions, calls for the liberalization of this ban have grown in recent years. Oregon's law permitting physician-assisted dying passed in 1997 is the oldest in the world. Mentally competent and physically able adults who have 6 months or less to live can get prescription for sedative medications they can take to end their lives. As of 2015, several states have enacted similar legislation, but it still remains illegal in the majority of the country.

The Human Connectome Project	United States	Hagmann P, Kurant M, Gigandet X, Thiran P, Wedeen VJ, Meuli R, Thiran, JP. Mapping human whole-brain structural networks with diffusion MRI. *PLoS ONE.* 2;e597:2007. Sporns O, Tononi G, Kotter R. The human connectome: A structural description of the human brain. *PLoS Comput Biol.* 1;e42:2005.	The Human Connectome Project aims to map all of the connections in the human brain in an effort to understand how cognitive processes emerge from their morphologic substrates. The project was launched in 2009 as part of broader efforts to increase neuroscience research. The human brain is highly complex and researchers face numerous challenges in data collection, mapping neuronal pathways, and correlating functional connectivity with anatomic connectivity. Data generated from the project could offer significant contributions to research in complex neurologic and psychological disorders.
Diversity, Equity, Inclusion, and Justice	United States	The APA issues its "Apology to Black, Indigenous and People of Color for Its Support of Structural Racism in Psychiatry."	
Classification of Mental Disorders	United States	The American Psychiatric Association publishes a text revision of DSM-5 (DSM-5-TR) in 2022	

ADHD, attention-deficit/hyperactivity disorder; AIDS, acquired immune deficiency syndrome; APA, American Psychiatric Association; CNS, central nervous system; CRF, corticotropin-releasing factor; CT, computed tomography; DSM, *Diagnostic and Statistical Manual of Mental Disorders;* ECT, electroconvulsive therapy; FDA, U.S. Food and Drug Administration; HIV, human immunodeficiency virus; MAOI, monoamine oxidase inhibitor; MMPI, Minnesota Multiphasic Personality Inventory; MRI, magnetic resonance imaging; NAMI, National Alliance for the Mentally Ill; NARSAD, National Alliance for Research on Schizophrenia and Depression; NIMH, National Institute for Mental Health; NMHA, National Mental Health Association; OCD, obsessive-compulsive disorder; PET, positron emission tomography; PTSD, posttraumatic stress disorder; SSRI, selective serotonin reuptake inhibitor; TR, text revision.

This table was conceived and developed by Ralph Colp Jr, M.D., who contributed to many editions of this book and who died in 2006. It was updated by several of the editors B. Sadock with the assistance of Kristel Carrington, and then by Robert Boland.

Appendix B

Glossary of Psychiatry and Psychology Terms

A

AA Alcoholics Anonymous.

AACAP American Academy of Child and Adolescent Psychiatry.

AACDP American Association of Chairmen of Departments of Psychiatry.

AADPRT American Association of Directors of Psychiatric Residency Training, Inc.

AAMC Association of American Medical Colleges.

AAP Association of Academic Psychiatry.

ability Capacity or competence to perform an act without previous training. *Compare* aptitude.

ablation Excision of part of the body, as in lobotomy or topectomy.

ablutomania Excessive interest in bathing and cleaning oneself; commonly observed in obsessive-compulsive disorder.

abnormal Term subject to considerable variability in definition and usage, roughly the equivalent of "psychopathologic," and defined according to several criteria: **1.** *Normative* or *statistical approach,* considers as abnormal any mental or behavioral activities that deviate from culturally determined averages or norms. **2.** *Subjective approach,* regards as abnormal or psychopathologic those phenomena that cause pain or suffering or induce a person

Telegram: @medical_k

www.konkur.in

to seek help. **3.** *Theoretical approach,* considers as abnormal any deviations from a theoretical concept of normal functioning that are indicative of psychiatric illness.

abortion Spontaneous or induced expulsion of an embryo or fetus before it has reached the stage of viability, that is, before about 20 weeks of gestation.

ABPN American Board of Psychiatry and Neurology.

abreaction A process by which repressed material, particularly a painful experience or a conflict, is brought back to consciousness; in this process, the person not only recalls but relives the repressed material, which is accompanied by the appropriate affective response. *See also* catharsis.

absence seizure PETIT MAL EPILEPSY.

absolute threshold Minimum amount of stimulus needed to produce a response.

abstinence The act of refraining voluntarily from some activity, or from the use of certain substances, such as food or drugs; in psychoanalysis, refers to refraining from sexual intercourse.

abstinence syndrome WITHDRAWAL SYNDROME; DISCONTINUATION SYNDROME.

abstract attitude ABSTRACT THINKING.

abstraction The process whereby thoughts or ideas are generalized and dissociated from particular concrete instances or material objects; concreteness in proverb interpretation suggests an impairment of abstraction, as in schizophrenia.

abstract thinking Thinking characterized by the ability to assume a mental set voluntarily, to shift voluntarily from one aspect of a situation to another, to keep in mind simultaneously various aspects of a situation, to grasp the essentials of a whole and to break a whole into its parts, to discern common properties, to plan, to assume make-believe attitudes, and to think or act symbolically. The capacity for abstract thinking is frequently impaired in patients with organic mental disorders and schizophrenia. Also called abstract attitude; categorical attitude. *Compare* concrete thinking.

abulia Inability to make decisions; lack of will.

Telegram: @medical_k

www.konkur.in

abuse 1. To attack or injure physically or psychologically, most commonly children, the older adults, and marital partners. *See also* battered child syndrome. **2.** To misuse substances such as drugs, illegal or prescribed, or alcohol so as to impair functioning.

acalculia Loss of ability to do calculations; not caused by anxiety or impairment in concentration. Occurs with neurologic deficit and learning disorder.

acarophobia Abnormal fear of minute animate (insects, worms) or inanimate (pins, needles) objects.

acatalepsia Severe mental deficiency characterized by the inability to reason or comprehend.

acataphasia Disordered speech in which statements are incorrectly formulated. Patients may express themselves with words that sound like the ones intended but that are not appropriate to the thoughts, or they may use totally inappropriate expressions.

acathexis Lack of feeling associated with an ordinarily emotion-charged subject; in psychoanalysis, denotes the patient's detaching or transferring of emotion from thoughts and ideas. Occurs in anxiety, dissociative, schizophrenic, and bipolar disorders. Also called decathexis. *Compare* cathexis.

accelerated interaction A term used in group therapy to refer to an extended group therapy session that may last for hours, sometimes a day. Alternate term for marathon group session.

accident proneness Tendency to have accidents as a result of psychological causes.

accreditation A voluntary process by which standards for hospitals and health facilities are approved by city or federal government agencies; may also refer to being credentialed by the American Board of Psychiatry and Neurology (ABPN). *See also* board-certified psychiatrist.

acenesthesia Loss of sensation of physical existence.

acetylcholine A neurotransmitter that causes cardiac inhibition, vasodilation, gastrointestinal peristalsis, and other parasympathetic effects; plays a critical role in memory, sleep, and the regulation of mood.

achluophobia Abnormal fear of the dark.

Telegram: @medical_k

www.konkur.in

acid Slang for lysergic acid diethylamide (LSD).

ACLP Academy of Consultation-Liaison Psychiatry

ACP American College of Physicians.

acquired immunodeficiency syndrome (AIDS) According to the U.S. Centers for Disease Control, "a disease, at least moderately predictive of a defect in cell-mediated immunity, occurring in a person with no known cause for diminished resistance to that disease. Such diseases include Kaposi sarcoma (KS), *Pneumocystis carinii* pneumonia (PCP), and other serious opportunistic infections." The disease is caused by the human immunodeficiency virus type 1 (HIV-1). *See also* AIDS dementia complex.

acromegaly Disorder marked by hypersecretion of growth hormone by the anterior pituitary resulting in characteristic enlargement of certain body structures, such as the head, hands, feet, lips, and jaw; often associated with somnolence, moodiness, and decreased libido.

acrophobia Abnormal fear of high places.

acting out Behavioral response to an unconscious drive or impulse that brings about temporary partial relief of inner tension; relief is attained by reacting to a present situation as if it were the situation that originally gave rise to the drive or impulse. Common in borderline states.

activity group psychotherapy Type of group therapy, introduced and developed by S. R. Slavson, designed for children and young adolescents, emphasizing emotional and active interaction in a permissive, nonthreatening atmosphere; the therapist interprets behavior and stresses reality testing.

actualization

Realization of one's full potential. *See also* individuation.

aculalia Nonsense speech associated with marked impairment of comprehension. Occurs in mania, schizophrenia, and neurologic deficit.

acute stress disorder Severe emotional reaction resulting from extreme environmental stress such as the death of a loved one, a disaster, or a catastrophic life situation. It usually remits within

Telegram: @medical_k

www.konkur.in

hours or days; however, if it persists for over a month it may evolved into a condition called posttraumatic stress disorder (PTSD).

ADAMHA Alcohol, Drug Abuse, and Mental Health Administration.

adaptation Process of fitting or conforming to the environment by behavioral or psychic changes that promote optimal functioning. *See also* adjustment.

adaptational approach In analytic therapy, consonant with Sandor Rado's formulations on adaptational psychodynamics, therapy focusing on the maladaptive patterns used by patients in the treatment sessions, on how those patterns developed, and on what the patients must do to overcome them and stabilize their functioning at self-reliant, adult levels. *See also* social adaptation.

adaptive behavior Any behavior that increases an organism's ability to adjust to a specific environment or situation.

ADD Attention-deficit disorder, usually referred to as Attention Deficit/Hyperactivity Disorder (ADHD).

addiction Repeated and increased use of a drug or chemical substance, the deprivation of which gives rise to symptoms of distress and an irresistible urge to use the agent again, leads to deterioration of physical and mental health. *See also* drug dependence.

ADHD Attention-deficit hyperactivity disorder.

adiadochokinesis Inability to perform rapid alternating movements. Occurs with neurologic deficit and cerebellar lesions.

adjustment Maladaptive reaction to identifiable circumstances or life events that is expected to remit when the stress ceases. In DSM-5, divided into the following subtypes based on symptoms: with anxiety, with depressed mood, with mixed anxiety and depressed mood, with disturbance of conduct, with mixed disturbance of emotions and conduct, and unspecified.

adjustment disorder Maladaptive reaction to identifiable circumstances or life events that is expected to remit when the stress ceases.

Adler, Alfred (1870–1937) Viennese psychiatrist and one of Freud's original followers who broke with him and introduced and

Telegram: @medical_k

www.konkur.in

developed the concepts of individual psychology, inferiority complex, and overcompensation. *See also* masculine protest.

adlerian Attributed to or described by Alfred Adler.

administrative psychiatry Psychiatry concerned with public affairs, policy-making, executive decisions, and the duties of persons in executive positions.

adolescence Period of growth from puberty to maturity. Its beginning is marked by the appearance of secondary sexual characteristics, usually at about age 12; termination is marked by the achievement of sexual maturity at about age 20. *See also* psychosexual development.

adolescent mania Signs of mania occurring in an adolescent as the result of substance abuse (including alcohol) or of antisocial behavior but not as the result of a true bipolar disorder.

adrenaline EPINEPHRINE.

adrenergic 1. Relating to nerve fibers, tracts, or pathways in which synaptic transmission is mediated by norepinephrine (e.g., the sympathetic division of the autonomic nervous system), more generally, to processes activated by epinephrine or norepinephrine. **2.** Relating to drugs (catecholamines) that mimic the actions of the sympathetic nervous system.

adrenergic system Nerve cells or fibers of the autonomic nervous system that employ norepinephrine as their neurotransmitter.

Advanced sleep phase circadian rhythm disorder A circadian rhythm sleep–wake disorder characterized by sleep–wake times that are earlier than conventional times; individuals with this disorder are referred to as “early birds” or “larks.”

adventitious reinforcement Responses that are reinforced accidentally by the coincidental pairing of response and reinforcement; such events may have clinical implications in the development of phobias or other neurotic behavior.

adverse effects Secondary, unfavorable reactions or results; usually referring to side effects of drugs.

adynamia Weakness and fatigability, a characteristic of neurasthenia and depression.

Telegram: @medical_k

www.konkur.in

adynamic ileus PARALYTIC ILEUS.

aerophagia Excessive swallowing of air. Seen in anxiety disorder.

affect The subjective and immediate experience of emotion attached to ideas or mental representations of objects. Affect has outward manifestations that may be classified as restricted, blunted, flattened, broad, labile, appropriate, or inappropriate. *See also* mood.

affect-fantasy Jung's term for an emotional-laden fantasy.

affectionate transference *See* transference.

affective disorder *See* MOOD DISORDER.

affective hallucination Hallucination in which the content is either grandiose or self-deprecatory or involves other features common to a depressive syndrome such as guilt, disease, or poverty.

affective interaction Interpersonal experiences and exchanges that are emotionally charged.

aftercare After hospitalization, a continuing program of rehabilitation designed to reinforce the effects of therapy and to help patients adjust to their environment.

ageism Prejudice or discrimination against a particular age group, especially the older adults.

ageusia Lack or impairment of the sense of taste; may be seen in depression and neurologic deficit.

aggression Forceful behavior, verbal or physical, usually directed against another person.

aggressive drive One of the two primal drives or instincts (the other is the sexual drive) in Freud's dual-instinct psychoanalytic theory. It is conceived of as an unconscious destructive drive or an impulse directed at oneself or another that aims toward dissolution and death and operates on the repetition–compulsion principle, in contrast to the sexual drive, which follows the pleasure–pain principle. Also called death instinct, Thanatos.

aging The process of growing old; in human physiology, aging is said to occur when there is a failure to replace cells in sufficient numbers to maintain full functional capacity.

Telegram: @medical_k

www.konkur.in

agitated depression Major depressive disorder with psychomotor agitation as a primary sign and symptom, characterized by restlessness, increased motor activity, and racing thoughts.

agitation State of anxiety associated with severe motor restlessness.

agnosia Inability to understand the import or significance of sensory stimuli; cannot be explained by a defect in sensory pathways or sensorium. In strict usage, diagnosis of agnosia implies an organic cerebral lesion; however, the term has also been used to refer to the selective loss or disuse of knowledge of specific objects due to emotional circumstances, as seen in certain schizophrenic, hysteric, and depressed patients. For types of agnosia, see the specific term.

agonist In pharmacology, a substance that excites the receptor sites of the cell and promotes or enhances a biologic response. *Compare* antagonist.

agoraphobia Morbid fear of open places or of leaving the familiar setting of the home; may be present with or without panic attacks.

agraphia Loss or impairment of a previously possessed ability to write.

aichmophobia Abnormal fear of pointed objects.

AIDS Acquired immunodeficiency syndrome.

AIDS dementia complex Neurologic complication of AIDS characterized by confusion, impaired judgment, impulsive behavior, and psychosis. Also called AIDS encephalopathy.

ailurophobia Abnormal fear of cats.

akathisia State of motor restlessness manifested by a compelling need to be in constant movement; may be seen as an extrapyramidal side effect of phenothiazine or other antipsychotic medication.

akinesia Lack of physical movement, as in the extreme immobility of catatonic schizophrenia; may also occur as an extrapyramidal effect of antipsychotic medication.

akinetic mutism Absence of voluntary motor movement or speech in a patient who is apparently alert (as evidenced by following eye movements). Seen in psychotic depression and catatonic states.

Al-Anon Organization of relatives of alcoholics, patterned after Alcoholics Anonymous, which promotes the discussion and resolution of common problems.

Alateen Organization directed to children of alcoholics, through group support, so that they may better understand their parents' alcoholism. *See also* Alcoholics Anonymous.

alcohol abuse and dependence Called alcohol use disorder in DSM-5. *See also* alcoholism.

alcohol amnestic disorder Alternative term for Korsakoff psychosis.

alcohol dementia WERNICKE SYNDROME.

alcoholic blackout Amnesia experienced by alcoholics concerning behavior during drinking bouts; usually indicates that reversible brain damage has occurred.

alcoholic deterioration Dementia and mental deterioration associated with chronic excessive alcohol use. Called dementia associated with alcoholism in DSM.

alcoholic hallucinosis Occurrence of hallucinations with a clear sensorium in a person with a history of heavy drinking and alcohol dependence; usually follows a prolonged drinking bout. *See also* Delirium tremens.

alcoholic psychosis Mental disorder that results from alcoholism and that involves organic brain damage, as in delirium tremens and Korsakoff psychosis.

Alcoholics Anonymous (AA) An organization of alcoholics formed in 1935 that uses certain group methods, such as inspirational-supportive techniques, to help rehabilitate chronic alcoholics.

alcohol idiosyncratic intoxication Syndrome of marked alcohol intoxication with subsequent amnesia for the period of intoxication produced by the ingestion of quantities of alcohol that would be insufficient to induce intoxication in most people. Also called pathologic intoxication.

alcohol intoxication Constellation of specific neurologic, psychological, and behavioral effects produced by the recent ingestion of alcohol; characteristically, the effects include slurred

Telegram: @medical_k

www.konkur.in

speech, motor ataxia, disinhibition of sexual or aggressive impulses, lability of mood, impairment of attention or memory, and impairment of judgment. *See also* intoxication.

alcoholism Excessive dependence or addiction to alcohol, usually to the point that the person's physical and mental health are threatened or harmed; may be episodic or continuous. Called alcohol use disorder in DSM-5.

alcohol withdrawal syndrome Symptom complex resulting from the cessation or reduction in alcohol intake in a person who has been drinking heavily; includes tremulousness, seizures (rum fits), hallucinations, and autonomic hyperactivity (delirium tremens). *See also* withdrawal syndrome.

Alexander, Franz (1891–1964) Hungarian psychoanalyst who founded the Chicago Institute for Psychoanalysis, developed the concept of corrective emotional experience and specificity hypothesis in psychosomatic disorders, and, in collaboration with Thomas French in 1946, identified most of the basic characteristics of brief dynamic psychotherapy.

alexia Loss of the power to understand the meaning of written or printed words and sentences. *Compare* dyslexia.

alexithymia Inability or difficulty in describing or being aware of one's emotions or moods; associated with depression, substance abuse, and posttraumatic stress disorder.

algophobia Abnormal fear of pain.

algorithm Graphic representation used as a set of instructions for solving diagnostic or clinical problems. Also called decision tree.

alienation In psychiatry, used to describe a person's feelings of detachment from self or society, to denote one's avoidance of emotional experiences, or to describe efforts to estrange oneself from one's own feelings. *Compare* relatedness. *See also* isolation.

alienist Obsolete term for a psychiatrist who offers expert opinion about a person's mental health or sanity.

allergic jaundice Relatively rare, unpredictable, non–dose-dependent hypersensitivity reaction after treatment with some phenothiazines; generally appears during the second to fourth weeks of therapy, resulting in hyperbilirubinemia and deposition of

Telegram: @medical_k

www.konkur.in

bile pigment in the skin and mucous membranes which causes a yellow appearance of the patient; an obstructive (cholestatic) type of jaundice manifested by predominantly conjugated (direct-reacting) hyperbilirubinemia, the presence of bilirubin in the urine, and an abnormally high plasma alkaline phosphatase.

alliance *See* therapeutic alliance.

allied health professional *See* paraprofessional.

alloplasty Adaptation to stress by attempting to change the environment. *Compare* autoplasty.

Allport's group relations theory Theory developed by Gordon W. Allport that a person's behavior is influenced by their personality and the need to conform to social forces; illustrates the interrelationship between group therapy and social psychology.

alogia Inability to speak because of mental deficiency or an episode of dementia.

alopecia Hair loss. *See* trichotillomania.

alpha (α) error TYPE 1 ERROR.

alpha waves As measured by an electroencephalogram (EEG), brain waves that are 8 to 13 Hz, indicating a relaxed, waking state.

ALS Amyotrophic lateral sclerosis.

alternating role Pattern characterized by periodic switching from one type of behavior to another.

altruism Regard for and dedication to the welfare of others; a term originated by the French philosopher Auguste Comte (1798–1857). In psychiatry, the term is closely linked with ethics and morals; Freud recognized altruism as the only basis for the development of community interest; Bleuler equated it with morality.

Alzheimer disease DEMENTIA OF THE ALZHEIMER TYPE.

AMA American Medical Association.

ambivalence Presence of strong and often overwhelming simultaneous contrasting attitudes, ideas, feelings, and drives toward an object, person, or goal; term coined by Bleuler, who differentiated three types: affective ambivalence, intellectual

Telegram: @medical_k

www.konkur.in

ambivalence, and ambivalence of the will. Commonly seen in schizophrenia and borderline personality disorder.

ambulatory schizophrenia A descriptive term refers to schizophrenic mental illness that is sufficiently well compensated so as not to require continuous hospitalization.

amentia Lack of intellectual development as a result of inadequate brain tissue. *Compare* dementia.

American Academy of Child and Adolescent Psychiatry (AACAP) Organization of child and adolescent psychiatrists, founded in 1953, whose objectives are to study and advance medical contributions to the knowledge and treatment of psychiatric illnesses of children and adolescents.

American Association of Chairmen of Departments of Psychiatry (AACDP) Organization of chairpersons of departments of psychiatry, founded in 1967, that concentrates on promoting medical education, research, and patient care, especially as they relate to psychiatry; prompting the growth and development of psychiatry; and providing a forum for discussion among chairpersons.

American Association of Directors of Psychiatric Residency Training, Inc. (AADPRT) Organization of training directors of U.S. psychiatric residency programs, founded in 1973, whose mandate is to oversee standards of approved residency criteria and to further psychiatric education.

American Board of Psychiatry and Neurology (ABPN) Group, founded in 1934 that sets the standards for teaching and training in psychiatry and neurology in American hospitals and training centers. Its members are from the American Medical Association, American Psychiatric Association, and American Neurological Association and is a member of the American Board of Medical Specialties. It conducts periodic examinations of those who have satisfactorily completed their training; upon passing the examination, candidates are certified to practice the specialty of psychiatry and/or neurology and/or child psychiatry. It also oversees continued certification for psychiatrists and neurologists.

www.konkur.in

American College of Physicians (ACP) Honorary organization of internists and related medical specialists, founded in 1915, that sponsors postgraduate courses for physicians as well as teaching and research scholarships.

American College of Psychiatrists (ACP) Honorary organization of senior psychiatrists, founded in 1963, established to honor persons who have made a significant contribution to the study and development of psychiatry in the United States.

American Law Institute formulation of insanity Legal definition of insanity whereby a person is absolved of criminal responsibility if, as a result of a mental disorder, he "lacks substantial capacity either to appreciate the wrongfulness of his conduct or to conform his conduct to the requirements of law." *See also* Durham rule; M'Naghten rule.

American Medical Association (AMA) National organization of medical doctors of all specialties, founded in 1847, whose mandate is to monitor the educational, training, and research concerns of the medical profession; plays an advisory role in national legislation related to health care and disseminates medical information.

American Neurological Association (ANA) National organization of neurologists, founded in 1875 that conducts research and educational programs; also elects members to the American Board of Psychiatry.

American Psychiatric Association (APA) Most important and largest professional organization of American physicians who specialize in the practice of psychiatry. The organization was founded in 1844 by 13 superintendents ("original thirteen") as the Association of Medical Superintendents of American Institutions for the Insane; in 1891, the name was changed to the American Medico-Psychological Association and in 1921 to its present name. Its purpose is to advance the development of psychiatric education, research, and practice in the United States.

American Psychoanalytic Association (APA) National organization of graduates of various psychoanalytic training programs, founded in 1911, mandated to establish and maintain

Telegram: @medical_k

www.konkur.in

standards for the field of psychoanalysis and the training of psychoanalysts and to encourage research; historically represents orthodox schools of classical psychoanalysis derived from Freudian theory.

American Psychological Association Founded in 1892, largest and most important organization of American psychologists who specialize in experimental, clinical, research, and educational psychology, and many other subspecialties in psychology; sometimes known as the “big APA” to distinguish it from the smaller American Psychiatric Association.

amimia Lack of ability to make gestures or to comprehend those made by others.

amines Organic compounds derived from ammonia by replacing hydrogen atoms with organic groups, such as the catecholamines.

amino acid Organic acid in which one of the CH hydrogen atoms has been replaced by NH_2; structured building blocks of proteins that function as neurotransmitters similar to the biogenic amines, probably in 60% to 70% of the synapses in the brain.

amnesia Disturbance in memory manifested by partial or total inability to recall past experiences. For types of amnesia, see the specific term.

amnestic aphasia, amnesic aphasia Disturbed capacity to name objects, even though they are known to the patient. Also called anomic aphasia.

amnestic disorder Mental syndrome in which impairment of memory is the predominant cognitive defect; in DSM-5, called major or minor neurocognitive disorder due to another medical condition.

amok Condition, usually associated with Malayan men, characterized by a sudden, unprovoked outburst of wild rage usually culminating in homicide.

amphetamine Central nervous system stimulant with a chemical structure and action closely related to the sympathomimetic amines; used to treat depression, attention-deficit hyperactivity

Telegram: @medical_k

www.konkur.in

disorder, hypersomnia, and narcolepsy; may be abused to prolong wakefulness and attentiveness.

amygdala Part of the basal ganglia complex in the dorsomedial portion of the temporal lobe: it and the hippocampus are major components of the limbic system and have been implicated in the production of memory, emotions, and violent behavior.

amyotrophic lateral sclerosis (ALS) Degenerative neuromuscular disease, caused by a slow virus, with an insidious onset beginning between the ages of 50 and 70; wasting begins in upper limbs, eventually spreading to the tongue, mouth, and palate. Degeneration of both pyramidal tracts above the medulla produces pseudobulbar palsy, which, when severe, results in impaired voluntary control of emotional reactions, which consequently, may be exaggerated, explosive, and quite inappropriate. Also called Lou Gehrig disease.

Amytal interview Psychiatric interview conducted with the patient having received an intravenous infusion of amobarbital (Amytal), which produces an altered state of consciousness during which repressed memories and feelings may be recalled or reexperienced; used in the treatment of dissociative states, psychogenic amnesia, and conversion disorder.

ANA American Neurological Association.

anaclitic Depending on others, especially as the infant on the mother; anaclitic depression in children results from an absence of mothering.

anaclitic therapy Psychotherapy characterized by allowing the patient to regress; used mainly in the treatment of psychosomatic disorders.

anal character Freud's term to describe persons who are perfectionistic, parsimonious, punctual, and stubborn.

analeptic PSYCHOMOTOR STIMULANT.

anal erotism Pleasurable experience felt by a child in the anal area during the anal phase of psychosexual development.

analgesia State in which one feels little or no pain.

Telegram: @medical_k

www.konkur.in

anal phase Second stage in psychosexual development, occurring when a child is between the ages of 1 and 3 years. During that period, activities, interests, and concerns are centered on the anal zone, and the pleasurable experience felt in that area is called anal erotism. *See also* infantile sexuality; psychosexual development.

analysand In psychiatry, the one who is being analyzed.

analysis in depth PSYCHOANALYSIS.

analysis of variance (ANOVA) Statistical technique designed to compare two or more groups of observations by which sets of measurements are investigated to find out to what extent they are determined by experimental influences or chance influences. *See also* variance.

analytic psychology Jung's system of psychology, characterized by a belief in the collective unconscious or objective psyche, the archetype, and the complex.

anamnesis Medical history of a patient, particularly used in connection with the patient's own recollections.

anancasm Repetitious or stereotyped behavior or thought usually used as a tension-relieving device. Alternate spelling, anankastic.

anankastic personality OBSESSIVE-COMPULSIVE PERSONALITY.

ancillary care Auxiliary, accessory, or secondary services provided in the treatment or rehabilitation of patients.

androgen Hormone that is produced in the testes and the adrenal glands and that stimulates activity of the accessory male sex organs, promotes development of male sex characteristics, or prevents changes in the latter following castration; for example, testosterone. *Compare* estrogen.

androgyny Combination of female and male characteristics in one person. *See also* bisexuality.

androphobia Irrational fear of men.

anergia Lack of energy.

anergic schizophrenic BURNED-OUT SCHIZOPHRENIC.

anesthesia Absence of sensation. *See also* hysterical anesthesia.

angel dust Street term for phencyclidine (PCP).

Telegram: @medical_k

www.konkur.in

anhedonia State of being unable to experience pleasure. *Compare* hedonism.

anima According to jungian psychology, the person's inner self, as opposed to the self that one presents to the outside world (persona).

Anna O A patient of Joseph Breuer and Sigmund Freud whose arm became paralyzed whenever she was unconsciously reminded of her feelings for her father (she had been sitting at his bedside with her arm pressed against the side of his bed at the time of his death). The motor disturbance represented an action that was associated with an objectionable infantile sexual impulse. Later identified as Bertha Pappenheim who became a noted feminist, social pioneer, and founder of the Jewish Women's Association.

anniversary reaction Behavior, symptoms, or dreams that occur at the same time of year as a significant past event.

anomia Inability to recall the names of objects.

anomic aphasia AMNESTIC APHASIA.

anomie Term, popularized by Émile Durkheim as a major cause for suicide, referring to a sense of alienation and despair resulting from the loss or weakening of previously valued norms, ideals, or goals.

anorectic Drug that decreases appetite.

anorexia nervosa Serious and sometimes life-endangering condition characterized by a disturbed body image and self-imposed severe dietary limitation, usually resulting in serious malnutrition; appetite usually remains intact.

anorgasmia Inability to achieve orgasm in the female. *See also* frigidity.

anosognosia Unawareness or nonacceptance of a neurologic deficit.

anosomnia Loss of ability to smell.

ANOVA Analysis of variance.

antagonist In pharmacology, a substance that reduces or blocks the action of another; for example, naloxone (Narcan) is used in the

Telegram: @medical_k

www.konkur.in

treatment of opioid overdose because it is reverses the effects of narcotics. *Compar*e agonist.

anterograde amnesia Loss of memory for events subsequent to the onset of the amnesia. *Compare* retrograde amnesia.

anthropology Study of humans in relation to distribution, origin, classification, and relationship of races, physical characteristics, environmental and social relations, and culture.

antianxiety drug ANXIOLYTIC.

anticholinergic Drug that blocks the actions of atropine; primarily used in the treatment of medication-induced movement disorders. *See also* antiparkinsonism drug.

anticholinergic effect Effect, such as a dry mouth and blurred vision, due to a blockade of the cholinergic (especially the parasympathetic) nerves; often seen as a side effect of therapy with phenothiazine and tricyclic antidepressant drugs.

anticipation Term implying careful planning or worrying, and premature but realistic expectation of dire and potentially dreadful outcomes, in goal-directed inner discomfort.

anticonvulsant Any drug with the ability to prevent the excessive discharge of neurons in the brain and thus lower the threshold for convulsions or seizures. Also called antiepileptic drug.

antidepressant drug Any of a class of psychotherapeutic drugs used in the treatment of pathologic depression. Two main categories are the cyclic antidepressants and the monoamine oxidase inhibitors; more recently, serotonergic agents such as fluoxetine. Lithium carbonate also has antidepressant activity in certain patients.

antiepileptic drug ANTICONVULSANT.

antimanic drug Drug used to alleviate the symptoms of mania; lithium is particularly effective in preventing relapses in bipolar disorder.

antiparkinsonism drug Drug that relieves the symptoms of parkinsonism and is effective in countering the extrapyramidal side effects often induced by antipsychotic drugs by acting on the central nervous system to diminish skeletal muscle tone and

Telegram: @medical_k

www.konkur.in

involuntary movements. Levodopa, the agent of choice for Parkinson disease, does not antagonize the extrapyramidal effects of antipsychotic drugs. Anticholinergic agents, such as benztropine and trihexyphenidyl, effectively counteract drug-induced parkinsonism but are now secondary drugs in the treatment of Parkinson disease.

antipsychotic Any of a class of psychotherapeutic drugs used to treat psychosis, particularly schizophrenia. Also called neuroleptic; major tranquilizer; ataractic drug.

antisocial behavior Behavior pattern of such marginal criminal types as racketeers, prostitutes, and illegal gamblers. Formerly called sociopathic behavior. In lay usage often confused with asociality. *See also* antisocial personality disorder.

antisocial personality disorder Disorder characterized by an inability to get along with other members of society and by repeated conflicts with individual persons and groups; common attributes include impulsiveness, egocentricity, hedonism, low frustration tolerance, irresponsibility, inadequate conscience development, exploitation of others, and rejection of authority and discipline. *See also* antisocial behavior.

Anton syndrome Disorder caused by a lesion in the occipital lobe of the brain that causes blindness which the patient denies experiencing.

Anxiety Unpleasurable emotional state associated with psychophysiological changes in response to an intrapsychic conflict; in contrast to fear, the danger or threat in anxiety is unreal. Psychological changes consist of an uncomfortable feeling of impending danger, an overwhelming awareness of being powerless, inability to perceive the unreality of the threat, prolonged feeling of tension, and exhaustive readiness for the expected danger; physiologic changes consist of increased heart rate, disturbed breathing, trembling, sweating, and vasomotor changes. *Compare* fear.

anxiety disorder Disorder in which anxiety is the most prominent disturbance or in which patients experience anxiety if they resist giving in to their symptoms. In DSM, anxiety disorders include

Telegram: @medical_k

www.konkur.in

separation anxiety disorder, selective mutism, panic disorder with agoraphobia, agoraphobia without history of panic disorder, social phobia, simple phobia, and generalized anxiety disorder.

anxiety disorders of childhood or adolescence Disorders characterized by chronic anxiety, unrealistic fears, hypersensitive autonomic responses, or fear of leaving home; patients are usually immature, inhibited, timid, approval-seeking, and apprehensive in new situations or places.

anxiety hysteria PHOBIC DISORDER.

anxiety neurosis As initially described by Sigmund Freud, a syndrome characterized by general irritability, anxious expectation, pangs of conscience, anxiety attacks, and phobias. Called generalized anxiety disorder in DSM.

anxiety state Disorder characterized by panic and anxious overconcern; somatic symptoms are often prominent.

anxiolytic Any of a class of psychotherapeutic drugs used to treat pathologic anxiety and its related symptoms; includes the benzodiazepines and buspirone. Also called antianxiety drugs; minor tranquilizers.

APA American Psychiatric Association; American Psychoanalytic Association; American Psychological Association.

apathetic withdrawal *See* withdrawal.

apathy Want of feeling or affect, a lack of interest and emotional involvement in one's surroundings; observed in certain types of schizophrenia and depression.

Apgar scores Measurements taken 1 and 5 minutes after birth to determine physical normality in the neonate; scores are based on color, respiratory rate, heartbeat, reflex action, and muscle tone.

aphasia Any disturbance in the comprehension or expression of language due to a brain lesion. For types of aphasia, see the specific term.

aphonia Loss of voice.

aphrodisiac Substance or drug that increases sexual desire.

apnea Temporary cessation of breathing. *See* obstructive sleep apnea syndrome.

Telegram: @medical_k

www.konkur.in

apoplexy Old classical term for cerebrovascular accident.

apperception Awareness of the meaning and significance of a particular sensory stimulus as modified by one's own experiences, knowledge, thoughts, and emotions. *See also* perception.

appetitive phase First stage in the sexual response cycle, as described by Masters and Johnson, characterized by sexual fantasies and the desire to have sex.

appropriate affect Emotional tone in harmony with the accompanying idea, thought, or speech.

apraxia Inability to perform a voluntary purposeful motor activity; cannot be explained by paralysis or other motor or sensory impairment. In constructive apraxia, a patient cannot draw two- or three-dimensional forms.

aptitude Potential to acquire competence or skill if trained. *Compare* ability.

archetype Jung's term for the symbols used by individuals to express the collective experience of the human race. *See also* collective unconscious.

arithmetic disorder DEVELOPMENTAL ARITHMETIC DISORDER.

arousal The establishment and maintenance of a physiologic or psychological state of being awake, alert, or responsive to stimuli. *See also* hyperarousal.

arteriosclerosis Degenerative condition marked by loss of elasticity, hardening, and thickening of the arteries, with progressive narrowing of their lumina and gradual obstruction to blood flow; organic mental disorder may develop when cerebral arteries are involved in the degenerative process.

artificial intelligence Computer production of a pattern of output that would be considered intelligent if displayed by human beings.

art therapy Treatment procedure that uses the spontaneous creative work of the patient; for example, persons make and analyze drawings, which are often expressions of their underlying emotional problems.

asociality Indifference to social values or customs, withdrawal from society, as seen in a recluse or a regressed schizophrenic person.

Telegram: @medical_k

www.konkur.in

Asperger syndrome Term previously used to describe a condition that develops in infancy and is associated with impaired social interaction and restricted and stereotyped patterns of behavior, but without significant delays in language or cognitive development. In DSM-5, the behavioral condition of Asperger syndrome is subsumed in Level I of the autism spectrum. *See also* autism spectrum disorder.

assertiveness training Behavior therapy that involves teaching frank and direct interpersonal expression of feelings and ideas.

assessment The evaluation of a patient that leads to diagnosis and treatment.

assimilation Subjective process that involves filtering the world through one's own system of knowledge, that is, taking in of new experience through one's established mental structure.

association Relation between ideas or feelings. *See* clang association; loosening of associations.

Association of American Medical Colleges (AAMC) Organization of American medical schools and teaching hospitals, founded in 1876, concerned with the advancement and improvement of medical education, biomedical research, and health care in the United States.

astasia-abasia Inability to stand or walk in a normal manner, even though normal leg movements can be performed in a sitting or lying down position; seen in conversion disorder.

astereognosis Inability to identify familiar objects by touch; cannot be explained by an impairment of elementary sensory pathways or a depressed sensorium. *See also* neurologic amnesia.

asthenic personality Disorder characterized by lack of enthusiasm, fatigability, lack of capacity for enjoyment, and low tolerance for stress. *See also* adynamia; anhedonia.

astraphobia, astrapophobia Abnormal fear of thunder and lightning.

asyndesis Disorder of language, commonly seen in schizophrenia, in which the patient combines unconnected ideas and images.

ataque de nervios A syndrome, usually found in Latin American cultures, characterized by uncontrollable shouting, crying,

Telegram: @medical_k

www.konkur.in

trembling, and physical or verbal aggression.

ataractic drug ANTIPSYCHOTIC.

ataxia Lack of coordination, either physical or mental. **1.** In neurology, refers to loss of muscular coordination. **2.** In psychiatry, the term "intrapsychic ataxia" refers to lack of coordination between feelings and thoughts; seen in schizophrenia and in severe obsessive-compulsive disorder.

athetosis Movement disorder characterized by involuntary, slow, writhing, worm-like movements of the fingers and extremities; a form of extrapyramidal dyskinesia.

atonia Lack of muscle tone. *See* waxy flexibility.

attachment According to John Bowlby, the affective tie between infant and mother or primary caregiver, the disruption of which heightens vulnerability to depression or anxiety. *See also* bonding.

attachment disorder of infancy Absence or disruption of behaviors that serve to anchor the infant to its mother or primary caregiver and that produce abnormal reactions in the infant's behavior.

attachment learning Theory that learning is enhanced in the presence of the person to whom one is attached or affiliated; applies especially to infant learning.

attention Concentration; the aspect of consciousness that relates to the amount of effort exerted in focusing on certain aspects of an experience, activity, or task.

attention-deficit hyperactivity disorder (ADHD) DSM-5 diagnosis for a childhood mental disorder characterized by a developmentally inappropriate short attention span, hyperactivity, and poor concentration that cause clinically significant impairment in functioning. The category subsumes abnormal behavior patterns that had historically been referred to by a variety of names, including hyperkinetic syndrome, hyperactive child syndrome, and minimal brain dysfunction. If hyperactivity is not present, the disorder is called attention-deficit disorder (ADD).

attitude Preparatory mental posture with which one receives stimuli and reacts to them.

Telegram: @medical_k

www.konkur.in

attributable risk Absolute incidence of a disease in exposed individuals that can be attributed to the exposure.

atypical In psychiatry, denoting an unusual or rare variant of a known disorder.

atypical child Child with distorted personality development; often used in connection with brain-damaged or autistic children.

atypical depression Diagnosis used to describe depression characterized by weight gain and hypersomnia rather than weight loss and insomnia.

atypical psychosis Disorder whose psychotic features are related to a specific culture (e.g., koro); a certain time or event (e.g., postpartum psychosis); or a unique symptomatology (e.g., Capgras syndrome). In DSM, depending on the specific syndrome, may be diagnosed as Other Specified Schizophrenia Spectrum and Other Psychotic Disorder.

audit *See* medical audit.

auditory agnosia The inability to recognize specific sounds in the context of intact hearing.

auditory amnesia NEUROLOGIC AMNESIA.

auditory hallucination Hallucination primarily involving sound.

aura 1. Warning sensations that a person usually experiences just before an epileptic seizure. **2.** Sensory prodrome that precedes a classic migraine headache.

authority figure Real or projected person in a position of power; transferentially, a projected parent.

autism *See* autistic thinking; infantile autism.

autistic spectrum disorder A range of behavioral abnormalities that begin in infancy and are characterized by deficits in social communication; failure to communicate; lack of empathy; abnormalities in eye contact; repetitive patterns of activities; stereotyped or absent speech; and either hyper- or hypoarousal to the environment. In DSM-5, autism spectrum disorder is classified into three levels based on degrees of impairment in speech and social interaction. *See also* Asperger syndrome; Rett syndrome; childhood disintegrative disorder.

Telegram: @medical_k

www.konkur.in

autistic thinking Thinking in which the thoughts are largely narcissistic and egocentric, with emphasis on subjectivity rather than objectivity, and without regard for reality; used interchangeably with autism and dereism.

autoerotic asphyxia Asphyxia caused by intentional strangulation while masturbating in order to intensify orgasm through reduction of oxygen blood flow to the brain. High risk of death.

autoerotism 1. Sexual arousal of oneself without the participation of another person; term coined by Havelock Ellis, which is presently used interchangeably with masturbation. **2.** In psychoanalysis, a primitive phase in object relationship development preceding the narcissistic stage; in narcissism, there is a love object, but there is no love object in autoerotism.

autogynephilia A gender identity disorder in which a male becomes sexually aroused by imagining themselves transformed into a woman.

automatic judgment Reflex performance of a way of acting based on a fixed set of beliefs or values.

automatic obedience Compliance to commands without exercising critical judgment; a feature of catatonia.

automatism Undirected behavior not controlled by conscious thought.

automysophobia Abnormal fear of smelling bad or of being unclean.

autonomic nervous system Part of the nervous system that functions outside of consciousness and that directs such visceral functions as respiration, heart rate, and digestion; subdivided into sympathetic (adrenergic) and parasympathetic (cholinergic) divisions.

autonomic side effect Disturbance of autonomic nervous function that may result from the use of antipsychotic or antidepressant drugs, particularly the phenothiazine and tricyclic derivatives. Common side effects of such agents include orthostatic hypotension, blurred vision, nasal congestion, dry mouth, and constipation; such anticholinergic effects are more prominent with tricyclic antidepressants than with phenothiazines.

Telegram: @medical_k

www.konkur.in

autonomous ego function Operation present at birth, such as perception, intuition, thinking, speaking, language, and aspects of motor development; first described by Heinz Hartmann. *See also* ego psychology.

autophobia Abnormal fear of being alone or of self.

autoplasty Adaptation to stress by changing intrapsychic processes. *Compare* alloplasty.

autoscopic psychosis Rare disorder, not officially listed in DSM-5, in which the patient sees a phantom or specter of their own body; usually psychogenic in origin, but may also be caused by lesions in the temporoparietal lobe of the brain.

autotopagnosia Inability to recognize and identify the parts of one's own body. *See also* finger agnosia.

auxiliary therapist Co-therapist. *See also* co-therapy.

average Central value in a frequency distribution around which other values are distributed. Also called the mean.

aversive conditioning AVERSIVE THERAPY.

aversive therapy Behavior therapy that involves the repeated coupling of an unpleasant or painful stimulus, such as an electric shock, with an undesirable behavior pattern in an effort to eliminate the undesirable behavior. Also called aversive conditioning.

avoidance and escape learning In escape learning, an animal learns a response to get out of a place where it does not want to be; for example, it jumps off an electric grid whenever the grid is charged. Avoidance learning requires an additional response: the same animal on the grid will learn to avoid a shock if it quickly pushes a lever when a light signal goes on. Escape learning and avoidance learning are two forms of aversive control using negative reinforcement; behavior that terminates the source of aversive stimuli is strengthened and maintained.

avoidant attachment According to Mary Ainsworth, a form of attachment in which children avoid returning to their mothers after being separated. Also called shyness disorder. *Compare* secure attachment. *See also* resistant attachment.

Telegram: @medical_k

www.konkur.in

avoidant disorder of childhood or adolescence Disorder of childhood or adolescence characterized by a persistent withdrawal or excessive shrinking from strangers.

avoidant personality disorder Personality disorder characterized by low self-esteem, hypersensitivity to rejection, and social withdrawal, but with a desire for affection and acceptance.

Avoidant/restrictive food intake disorder Disorder characterized by an avoidance or lack of interest in food, resulting in severe weight loss, nutritional deficiency, and failure to thrive; a DSM-5 diagnosis. Previously called feeding disorder of infancy or early childhood.

axon Single structure in a nerve cell that conducts nervous impulses away from the cell body and its dendrites.

B

barbiturate Any of a class of sedative-hypnotic drugs derived from barbituric acid that acts as a central nervous system depressant and readily produces psychic and physical dependence; for example, phenobarbital, secobarbital, thiopental sodium.

basal ganglia Collectively, the corpus striatum, substantia nigra, subthalamic nucleus, and substantia innominata, which are involved in disorders of movement, thought processes, affect, cognition, and symptoms of psychosis.

basic anxiety As conceptualized by Karen Horney, the main-spring from which neurotic trends get their intensity and pervasiveness, characterized by vague feelings of loneliness, helplessness, and fear of a potentially hostile world. *See also* anxiety.

basic benefits Insurance term that refers to minimum payments or coverage for medical or psychiatric care.

bathophobia Abnormal fear of depths.

battered child syndrome Physical damage to a child sustained as a result of repeated beatings, usually by a parent, parent surrogate, or relative. *See also* abuse.

battery tests Individual tests used together make up a psychological battery; for example, Halstead–Reitan Neuropsychological Battery.

Telegram: @medical_k

www.konkur.in

A test battery can give more information about different areas of function than an individual test and can increase the level of confidence if there is a positive correlation between them.

BEAM Brain electrical activity mapping.

Beard, George M. (1839–1883) American psychiatrist who in 1869 introduced the term “neurasthenia.”

Beers, Clifford (1876–1943) Author of *A Mind That Found Itself* (1909) and who is generally considered to have founded the mental hygiene movement.

behavior Sum total of the psyche that includes impulses, motivation, wishes, drives, instincts, and cravings, as expressed by a person’s behavior or motor activity. Also called conation.

behavioral disorders of childhood *See* disruptive behavior disorders.

behavioral medicine Application of principles of behavior therapy to the prevention, diagnosis, treatment, and rehabilitation of medical disorders; applies to such areas as stress prevention and reduction, pediatric and adult patient management and compliance, pain control, and life-style modification. Biofeedback relaxation training, behavior therapy, and hypnosis are important treatment modalities.

behavioral neurology Field of study that attempts to combine psychiatry and neurology to explain abnormal behavior as a disorder of brain metabolism or as a result of structural alterations of the central nervous system.

behavioral science Scientific discipline concerned with any aspect of human behavior, including interpersonal relationships, development, values, experiences, and activities; the behavioral sciences include sociology, psychology, psychiatry, anthropology, and ethology.

behavior contract Therapeutic strategy that rewards a person for a desired behavior.

behaviorism School of psychological thought founded by John B. Watson that regards only measurable and observable behavior as the appropriate subject matter for human psychology; holds that human behavior can be described in terms of principles that do not

Telegram: @medical_k

www.konkur.in

require consideration of unobservable mental events, such as ideas and emotions. *See also* behavior therapy.

behavior modification *See* behavior therapy.

behavior therapy Psychiatric treatment modality that focuses on overt and objectively observable behavior and uses various conditioning techniques derived from learning theory to directly modify the patient's behavior; aims exclusively at symptomatic improvement, without addressing psychodynamic causation. Behavior therapy techniques include assertiveness training, aversive therapy, flooding, implosion, reciprocal inhibition, and desensitization, shaping, and systematic desensitization. *See also* behaviorism; conditioning.

Bender-Gestalt Test Psychological test, designed by Lauretta Bender, which measures the subject's ability to reproduce a set of geometric designs: is useful for measuring visuomotor coordination as a means of detecting brain damage. Also called visual motor gestalt test.

benzodiazepines Any of a group of drugs used mainly to treat anxiety; also used as sedatives, muscle relaxants, anticonvulsants, anesthetics, and hypnotics.

bereavement Feeling of grief or desolation, especially at the death or loss of a loved one. *See also* mourning.

bestiality Sexual deviation in which a person engages in sexual relations with an animal. *See also* zoophilia.

beta (β) error TYPE 2 ERROR.

beta waves As measured by an electroencephalogram (EEG), brainwaves that are between l4 and 30 Hz; altered in certain epileptic conditions.

bias In statistics, an error in the construction of the assessment instrument that favors one outcome over another.

binge eating disorder Eating disorder characterized by recurrent episodic, uncontrolled, compulsive, and rapid ingestions of large amounts of food over a short period of time (binge eating) followed by feelings of guilt; a DSM-5 diagnosis, differentiated from bulimia

Telegram: @medical_k

www.konkur.in

nervosa by an absence of compulsive compensatory behaviors to achieve weight loss.

binge eating, binge and purge *See* bulimia nervosa.

biodynamics System of psychoanalytic psychiatry, introduced by Jules H. Masserman, which holds that all behavior results from the organism's genetic potentialities, from the various paths and speed of maturation, and from its unique experiences.

biofeedback Provision of information to a person regarding one or more physiologic processes in an effort to enable the person to gain some element of voluntary control over bodily functions that normally operate outside consciousness. *See also* learned autonomic control.

biogenic amine Endogenous compound believed to play an important role in brain function as a central synaptic neurotransmitter substance; biogenic amines include the catecholamines (epinephrine, norepinephrine, dopamine) and serotonin, an indolamine.

biogenic amine hypothesis Theory of mood disorders which proposes that depression is associated with an absolute or relative deficiency of catecholamines, particularly norepinephrine, at functionally important receptor sites in the brain; conversely, elation may be associated with an excess of such amines.

biologic psychiatry School of psychiatric thought emphasizing biochemical, neurologic, and pharmacologic factors in the causation and treatment of psychiatric disorders.

biologic rhythm Periodic variation in physiologic and psychological functions. For example, a circadian rhythm shows aperiodicity of about 24 hours; an ultradian rhythm has a cycle shorter than 1 day; an infradian rhythm is longer than 1 day.

bipolar I Bipolar disorder in which a patient meets the criteria for a full manic episode, usually sufficiently severe to require hospitalization.

bipolar II Bipolar disorder in which a patient has at least one depressive episode and at least one hypomanic episode.

bipolar disorder A mood disorder in which the patient exhibits both manic and depressive episodes separated by various lengths of

Telegram: @medical_k

www.konkur.in

time. Previously referred to as manic–depressive illness.

birth trauma Otto Rank's term to describe the birth process, which he considered the basic source of anxiety in human beings.

bisexual Denoting or characterized by sexual attraction to and sexual contact with members of both sexes.

bisexuality Existence of the qualities of both sexes in the same person. Freud postulated that the sexes differentiated both biologically and psychologically from a common core; that differentiation between the two sexes was relative, rather than absolute; and that regression to the common core occurs to varying degrees in both normal and abnormal conditions. *Compare* bisexual; heterosexuality; homosexuality. *See also* androgyny.

bizarre delusion False belief that is patently absurd or fantastic.

blackout *See* alcoholic blackout.

black-patch syndrome Psychosis induced by sensory deprivation as a result of eye patches used after cataract surgery.

blank screen Neutral backdrop on which the patient projects a gamut of transferential irrationalities; passivity of analysts allows them to act as blank screens.

Bleuler, Eugen (1857–1939) Swiss psychiatrist known for his important studies in schizophrenia, a term he coined and preferred over the earlier term "dementia praecox."

blind spot In psychiatry, an area of a person's personality of which they are totally unaware; unperceived areas are repressed, since their recognition would arouse painful or unpleasant emotions. In the course of group or individual psychotherapy, such blind spots often appear obliquely as projected ideas, intentions, and emotions. *See also* projection; scotoma.

blocking Involuntary cessation or interruption of thought processes or speech because of unconscious emotional factors. Also called thought deprivation.

Blood–brain barrier Series of biologically active membranes that regulate the passage of substances into and out of the central nervous system; maintains a chemical homeostasis between the cerebrospinal fluid and the venous and arterial systems.

Telegram: @medical_k

www.konkur.in

blood level In psychiatry, the measurement of the concentration of drugs in plasma or serum to determine their therapeutic effect.

blunted affect Disturbance of affect manifested by a severe reduction in the intensity of externalized feeling tone; one of the fundamental symptoms of schizophrenia, as outlined by Eugen Bleuler.

board-certified psychiatrist Psychiatrist who has passed the examinations of the American Board of Psychiatry and Neurology (ABPN). *See also* accreditation.

body dysmorphic disorder Disorder characterized by an unrealistic concern that part of the body is deformed. Included on the obsessive-compulsive spectrum in DSM-5. Also called dysmorphophobia.

body-focused repetitive behavior disorders Descriptive term for a group of behaviors consisting of compulsions that damage one's own body, such as skin biting, lip biting, or nail biting; not a diagnosis in DSM-5.

body image Conscious and unconscious perception of one's body at any particular time.

body language Expression of thoughts and feelings by body posture and movement.

bonding Nonsexual feelings of love, respect, and communality among individuals of the same sex. Specifically, a mother's feelings for her infant, but often used to refer to the general mother–infant relationship; fathers often bond to infants. *See also* attachment.

borderline intellectual functioning A term previously attributed to individuals with below-average cognitive ability (IQ in the 70–80 range) whose intellectual impairment did not meet criteria for intellectual disability (IQ below 70). This condition is not clearly differentiated from mild intellectual disability and may be the focus of clinical attention, however, no definitive criteria for diagnosis exist in DSM-5. *See also* intellectual disability.

borderline personality disorder Personality disorder marked by instability in various areas, impulsiveness, suicidal acts, self-

Telegram: @medical_k

www.konkur.in

mutilations, identity problems, and feelings of emptiness or boredom.

borderline psychosis BORDERLINE STATE.

borderline state State in which the symptoms are so unclear or transient that it is difficult to classify the patient as psychotic or nonpsychotic. Also called borderline psychosis.

boufée délirante A syndrome, observed in West Africa and Haiti, characterized by a sudden outburst of agitated and aggressive behavior, marked confusion, and psychomotor excitement. It is sometimes accompanied by visual or auditory hallucinations or paranoid ideations. May resemble an episode of brief psychotic disorder.

Bowlby, John (1907–1990) British psychoanalyst who formulated the theory of attachment to describing the mother–infant relationship. *See also* attachment; bonding.

bradykinesia Slowness of motor activity, with a decrease in normal spontaneous movement.

bradylalia Abnormally slow speech, common in depression.

bradylexia Inability to read at normal speed.

brain That part of the central nervous system contained within the cranium; includes the cerebrum, midbrain, cerebellum, pons, and medulla.

brain abscess Localized, suppurative, infectious process involving a part of the brain; may produce an organic mental disorder as well as focal neurologic signs.

brain electrical activity mapping (BEAM) Response of brain electrical activity to sensory stimuli which is recorded by computer averaging techniques that produce a topographic color map of brain activity.

brain imaging Radiologic techniques that allow assessment in vivo of structural and functional neuroanatomy; include computed tomography (CT), magnetic resonance imaging (MRI), regional cerebral blood flow (rCBF), positron emission tomography (PET), and brain electrical activity mapping (BEAM).

Telegram: @medical_k

www.konkur.in

brain metabolism Chemical changes in the brain that convert small molecules into large ones (anabolism) and large molecules into small ones (catabolism), and that account for cellular function and repair.

brain stem Area of the brain comprising the mesencephalon, pons, and medulla oblongata, whose basic functions concern respiration, cardiovascular activity, sleep, and consciousness; also the site of the ascending biogenic amine (dopamine, noradrenalin, serotonin) pathways to higher brain areas.

brain syndrome *See* organic mental disorder.

brainwashing Any technique designed to manipulate human thought or action against the desire, will, or knowledge of the person involved; usually refers to systematic efforts to indoctrinate nonbelievers. In DSM-5 diagnosed as "identity disturbance due to prolonged and intense coercive persuasion." Also called coercive persuasion.

brain wave Rhythmic wave-like electrical pattern in an encephalogram.

Brawner decision *See* Model Penal Code.

breathing-related sleep disorder Characterized by sleep disruption leading to excessive sleepiness or insomnia caused by a sleep-related breathing disturbance; three types of breathing-related sleep disorders include obstructive sleep apnea, central sleep apnea, and sleep-related hypoventilation.

Breuer, Josef (1842–1925) Viennese physician who collaborated with Freud in studies of cathartic therapy, as reported in *Studies on Hysteria* (1895); he withdrew as Freud proceeded to introduce psychoanalysis, but left important imprints on that discipline, such as the concepts of the primary and secondary processes.

brief psychotherapy Psychotherapy in which the sessions are limited to 10 to 15 in number and during which time attempts to modify behavior occur; used in both individual and group settings.

brief psychotic disorder DSM-5 category for a psychosis of less than 4 weeks' duration, with sudden onset after a major stress. Also called brief reactive psychosis.

brief reactive psychosis *See* brief psychotic disorder.

Telegram: @medical_k

www.konkur.in

Brigham, Amariah (1798–1849) One of the founders of the American Psychiatric Association and the first editor of its journal.

Brill, A. A. (1874–1948) First American analyst (1908) who translated several of Freud's more important works, was active in the formation of the New York Psychoanalytic Society (1911), and remained a foremost propagator of psychoanalysis as a lecturer and writer.

Briquet syndrome Alternate term for somatic symptom disorder.

broad affect Normal range (varies both within and among cultures) of the expression of a subjectively experienced feeling state (e.g., euphoria, anger, sadness); normal expression of affect involves variability in facial expression, pitch of voice, and hand and body movements.

Broca aphasia MOTOR APHASIA.

brooding compulsion INTELLECTUALIZATION.

bruxism Grinding or gnashing of the teeth, typically occurring during sleep.

bulimia nervosa Recurrent episodic, uncontrolled, compulsive, and rapid ingestion of large amounts of food over a short period of time (binge eating) followed by self-induced vomiting, use of laxatives or diuretics, fasting, or vigorous exercise in order to prevent weight gain (binge and purge); weight is not severely lowered.

burned-out schizophrenic Chronic schizophrenia characterized by a person who is apathetic and withdrawn, with minimal florid psychotic symptoms but with persistent and often severe schizophrenic thought processes. Also called anergic schizophrenia.

burnout Syndrome of physical or emotional exhaustion considered to be a stress reaction to unrelenting performance and emotional demands stemming from one's occupation; symptoms include impaired work performance, fatigue, insomnia, increased susceptibility to physical illness, and reliance on alcohol (or other substances) with a tendency to escalation into physiologic dependency or possibly suicide.

Telegram: @medical_k

www.konkur.in

butyrophenone Any of a class of antipsychotic drugs of which haloperidol (Haldol) is a representative example.

C

C.A. Chronologic age.

cacodemonomania Condition in which patients think they are possessed by a devil or other evil spirit.

caffeine Alkaloid found in coffee, tea, and cola drinks which acts as a psychomotor stimulant; caffeine intoxication results from the excessive ingestion of caffeine.

Canadian Psychiatric Association (CPA) National organization of Canadian psychiatrists whose purpose is to further the development of psychiatric education, research, and practice in Canada.

cannabis *See* marijuana.

canonical correlation Multivariate technique used in statistics for simultaneously finding the relationship of linear combinations of two or more predictors and two or more outcomes.

Capgras syndrome Delusional disorder in which the patient believes that persons in the environment are not their real selves but are doubles imitating the patient or imposters imitating someone else.

capitation Prepayment fee based on a fixed number of persons that covers all health care services.

care and protection proceedings Intervention by a court on behalf of a child when the parents or caretakers provide inadequately for the child's welfare.

carebaria Sensation of discomfort or pressure in the head.

caregiver 1. Any person involved in the identification, prevention, or treatment of illness or disability. **2.** In child psychiatry, a person who tends to the needs of an infant or child. Also called caretaker.

case-control study Study in which the illness is the dependent variable, already being present for the subject to be identified; such studies are therefore retrospective.

Telegram: @medical_k

www.konkur.in

case history study Retrospective study that samples persons with a given disorder.

case register Medical records in central data banks.

castration anxiety Anxiety concerning a fantasied loss of or injury to the genitalia.

castration complex In psychoanalytic theory, a group of unconscious thoughts and motives that are referable to the fear of losing the genitalia, usually as punishment for forbidden sexual desires.

catalepsy Condition in which persons maintain the body position into which they are placed; observed in severe cases of catatonic schizophrenia. Also called waxy flexibility; cerea flexibilitas. *See also* command automatism.

cataphasia VERBIGERATION.

cataplexy Temporary sudden loss of muscle tone, causing weakness and immobilization; can be precipitated by a variety of emotional states, and it is often followed by sleep; commonly seen in narcolepsy.

catastrophic anxiety Anxiety associated with cognitive disorders when patients are aware of their defects in mentation; the anxiety may be overwhelming.

catathymia Situation in which elements in the unconscious are sufficiently affect-laden to produce changes in conscious functioning.

catathymic crisis Suddenly occurring, isolated, and nonrepetitive act that develops from a state of intolerable tension.

catatonia Clinical syndrome consisting of marked behavioral irregularities, which may include motoric excitement or immobility, negativism, stupor, echolalia, or echopraxia. In DSM-5, catatonia may be a stand-alone diagnosis; a feature of schizophrenia; associated with other mood/psychotic disorders; associated with medications or substance use; or due to an underlying medical condition.

catatonic excitement Excited, uncontrollable motor activity seen in catatonic schizophrenia. Patients in catatonic state may suddenly

Telegram: @medical_k

www.konkur.in

erupt into an excited state and may be violent.

catatonic posturing Voluntary assumption of an inappropriate or bizarre posture, generally maintained for long periods of time. May switch unexpectedly with catatonic excitement.

catatonic rigidity Fixed and sustained motoric position that is resistant to change.

catatonic schizophrenia A rare type of schizophrenia; no longer included in DSM-5. *See* catatonia.

catatonic state State characterized by muscular rigidity and immobility (catatonia), usually associated with schizophrenia.

catatonic stupor Stupor in which patients ordinarily are well aware of their surroundings.

catchment area In psychiatry, a circumscribed geographic area served by a particular community mental health center.

catecholamine Biogenic monoamine containing a catechol group. Norepinephrine, epinephrine, and dopamine are catecholamines with important effects on peripheral and central nervous system activity.

categorical attitude ABSTRACT THINKING.

categorical thought Term introduced by Jean Piaget to refer to abstract thinking. *See also* secondary process.

catharsis Release of ideas, thoughts, and repressed materials from the unconscious, accompanied by an affective emotional response and relief; commonly observed in the course of both individual and group psychotherapy, but can also occur outside therapy. *See also* abreaction; conversational catharsis.

cathexis In psychoanalysis, a conscious or unconscious investment of psychic energy in an idea, a concept, an object, or a person. *Compare* acathexis.

CAT scan Incorrect but commonly used variant of “CT scan.” *See also* computed tomography.

cat’s cry syndrome *See* cri-du-chat syndrome.

Cattell Infant Intelligence Scale Psychological test used to assess general motor and cognitive development in infants aged 3 months to 2 years.

Telegram: @medical_k

www.konkur.in

causalgia Burning pain that may be either organic or psychic in origin.

cause–effect relationship Relationship in which one action causes a specific reaction.

causalgia Burning pain that may be organic or psychic in origin.

cenesthesia Change in the normal quality of feeling tone in a part of the body.

central nervous system (CNS) The spinal cord and the brain.

central sleep apnea Dyssomnia characterized by repeated episodes of apnea, shallow breathing, and/or irregular breathing that result from a periodic failure of the central nervous system mechanisms to stimulate breathing. There are three subtypes in DSM-5: idiopathic, Cheyne–Stokes breathing pattern, and comorbid with opioid use. *Compare* obstructive sleep apnea.

cephalalgia Headache.

cerea flexibilitas Condition of a person who can be molded into a position that is then maintained; when an examiner moves the person's limb, the limb feels as if it were made of wax. Also called catalepsy; waxy flexibility. Seen in schizophrenia.

cerebral arteriosclerosis Arteriosclerotic involvement (hardening) of arteries of the brain; may lead to organic mental disorder.

cerebrovascular accident Cerebral hemorrhage, thrombosis, or embolism. Also called stroke; apoplexy.

character Constellation of relatively fixed personality traits and attributes that govern a person's habitual modes of response.

character analysis Psychoanalytic treatment that concentrates on character defenses.

character defense Personality trait that serves an unconscious defensive purpose.

character disorder Pattern of personality characterized by maladaptive, inflexible behavior.

Charcot, Jean M. (1825–1893) French neurologist noted for describing hysteria and treating it by means of hypnosis; Freud based much of his early work on Charcot's pioneering studies in hysteria.

chemical dependence *See* drug dependence.

Telegram: @medical_k

www.konkur.in

chemotherapy DRUG THERAPY.

child abuse *See* battered child syndrome.

child analysis Application of psychoanalytic principles to the treatment of the child.

childhood disintegrative disorder A condition defined by marked regression in several functional domains (e.g., intellectual, social, motor, and language skills) after at least 2 years of normal development; diagnosis is typically made in children who are between 3 and 4 years of age. In DSM-5, childhood disintegrative disorder is a subset of autism spectrum disorder.

childhood schizophrenia DSM term for pervasive developmental disorder. *See* autistic spectrum disorder.

child-onset fluency disorder *See* stuttering.

chi square Statistical technique in which variables are categorized in order to determine whether a distribution of scores is due to chance or to experimental factors.

chlorpromazine Aliphatic phenothiazine derivative used primarily as an antipsychotic agent and in the treatment of nausea and vomiting.

cholinergic Relating to nerve fibers, tracts, or pathways in which synaptic transmission is mediated by acetylcholine; for example, parasympathetic nerve fibers and somatic motoneurons; also refers to processes activated by acetylcholine.

chorea Movement disorder characterized by random and involuntary quick, jerky, purposeless movements. *See also* extrapyramidal dyskinesia; Huntington chorea.

chronic fatigue syndrome An illness characterized by 6 months or more of severe, debilitating fatigue, often accompanied by myalgia, headaches, pharyngitis, low-grade fever, cognitive complaints, gastrointestinal symptoms, and tender lymph nodes. The cause is unknown.

chronobiology Study of biologic rhythms that objectively explores and quantifies mechanisms of time structure in biologic systems.

chronologic age (C.A.) *See* intelligence quotient.

Telegram: @medical_k

www.konkur.in

chronophobia Fear of time characterized by panic, anxiety, and claustrophobia. Sometimes called prison neurosis, since almost all prisoners are affected by it in some fashion.

circadian rhythm *See* biologic rhythm.

circadian rhythm sleep disorder A set of dyssomnias involving a misalignment between desired and actual sleep periods. Includes delayed sleep phase, jet lag, and work shift.

Circadian Rhythm Sleep–Wake Disorders A group of sleep disorders characterized by disruption in sleep that alters a patient's circadian rhythm and is associated with insomnia or excessive sleepiness. There are six types of circadian rhythm sleep–wake disorders in DSM-5: delayed sleep phase type, advanced sleep phase type, irregular sleep–wake type, non–24-hour sleep–wake type, shift work type, and unspecified type.

circumstantiality Disturbance in the associative thought and speech processes in which a patient digresses into unnecessary details and inappropriate thoughts before communicating the central idea; observed in schizophrenia, obsessional disturbances, and certain cases of dementia. *See also* tangentiality.

civil commitment In statutes governing hospitalization of the mentally ill, a legal term meaning a warrant for imprisonment; as recommended by the American Psychiatric Association and the American Bar Association, "commitment" has been replaced by "hospitalization."

CJD Creutzfeldt–Jakob disease.

claims review Method of peer review consisting of the examination of claims for the reimbursement of treatment after it has been rendered.

clairvoyance Extrasensory perception in which there is an alleged ability to perceive that which is out of sight or cannot be seen.

clang association, clanging Association or speech directed by the sound of a word rather than by its meaning; punning and rhyming may dominate the person's verbal behavior; seen most frequently in schizophrenia or mania.

classical conditioning *See* conditioning.

classic migraine *See* migraine.

Telegram: @medical_k

www.konkur.in

claustrophobia Abnormal fear of closed or confining spaces.

client-centered psychotherapy Nondirective form of psychotherapy, originated by Carl Rogers, in which the therapeutic process focuses on the patient's own thinking and feeling which the therapist merely helps to clarify through understanding and empathy; developed as a reaction against the authoritativeness and interpretation of the more traditional psychotherapies.

climacteric Menopause and immediate postmenopausal period in women; sometimes used to refer to the same age period in men.

clinical psychologist Psychologist with additional training and experience in a clinical setting who specializes in evaluation and treatment of mental disorders.

clinical psychology Branch of psychology concerned with the application of psychological principles to the prevention, treatment, and understanding of psychopathology.

clonic convulsion An involuntary, violent muscular contraction or spasm in which the muscles alternately contract and relax. Characteristic phase in grand mal epileptic seizure.

clouding of consciousness Any disturbance of consciousness in which the person is not fully awake, alert, and oriented. Occurs in delirium, dementia, and cognitive disorder.

cluster suicides Suicides that occur together in geographic groups or in temporal association. *See also* copy-cat suicides.

cluttering Disturbance of fluency involving an abnormally rapid rate and erratic rhythm of speech that impedes intelligibility; the affected individual is usually unaware of communicative impairment.

CNS Central nervous system.

cocaine Alkaloid, obtained from leaves of the coca plant, whose systemic effects include striking central nervous system stimulation manifested by garrulousness, restlessness, excitement, and feelings of increased muscular strength and mental capacity; also an effective topical local anesthetic.

coefficient of correlation Statistical term referring to the relation between two sets of paired measurements, correlation coefficients are positive, negative, or curvilinear, depending on whether the

Telegram: @medical_k

www.konkur.in

variations are in the same direction, the opposite direction, or both directions. They can be computed in a variety of ways, the most common being the product–moment method (r); another method is rank correlation (p). Correlation coefficients are intended to show degree of relation, but they do not imply a causal relationship between variables.

coercive persuasion BRAINWASHING.

coexistent culture Alternative system of values, norms, and patterns for behavior; the group therapy experience often leads to an awareness of other systems as legitimate alternatives to one's own system.

cognition Mental process of knowing and becoming aware; an ego function closely associated with judgment.

cognitive-behavioral therapy (CBT) A form of psychotherapy in which the focus of treatment is on changing the thoughts and behaviors that are related to specific symptoms. The aim of treatment is on symptom reduction and improved functioning.

cognitive development Progressive acquisition of conscious thought and problem-solving abilities that begins in infancy and follows an orderly sequence of more or less discrete stages.

cognitive dissonance Incongruity in a person's beliefs, thoughts, or actions that produces an uncomfortable tension state that the person is motivated to change.

cognitive therapy Structured and directive form of therapy developed by Aaron T. Beck that emphasizes how patients think about themselves and the future; consists of reversing the cognitive triad of negative expression of self, negative expression of future, and negative view of the world.

cognitive triad Belief system described by the psychiatrist Aaron Beck that is present in depressed persons who have a negative view of the self, a negative interpretation of present and past experience, and a negative expectation of the future.

cohesion *See* group cohesion.

cohort Group chosen from a well-defined population; cohort studies provide direct estimates of risk associated with a suspected causal

Telegram: @medical_k

www.konkur.in

factor.

coitus interruptus Sexual intercourse that is interrupted before the man ejaculates.

cold turkey Abrupt withdrawal from opiates, or any addictive central nervous stimulant, without the benefit of methadone or other drugs; a term originated by drug addicts to describe their chills and consequent goose-flesh. Abstinence-oriented therapeutic communities use this type of detoxification.

collective experience Term coined by S. R. Slavson for the common emotional experiences of a group of people, which, in the setting of group psychotherapy, accelerates the therapeutic process. Identification, mutual support, reduction of ego defenses, sibling transferences, and empathy help integrate the individual member into the group.

collective unconscious Psychic contents outside the realm of awareness that are common to mankind in general. Carl Jung, who introduced the term, believed that the collective unconscious is inherited and derived from the collective experience of the species, that it transcends cultural differences, and that it explains the analogy between ancient mythologic ideas and the primitive projections observed in some patients who have never been exposed to those ideas. Also called objective psyche.

coma State of profound unconsciousness from which a person cannot be roused, with minimal or no detectable responsiveness to stimuli; seen in injury or disease of the brain, in such systemic conditions as diabetic ketoacidosis and uremia, and in intoxications with alcohol and other drugs. Coma may also be seen in severe catatonic states and in hysteria.

coma vigil Coma in which the eyes remain open; typically seen in acute organic mental syndromes associated with systemic infection.

combat fatigue Disabling physical and mental reaction to the stresses of military battle; now called posttraumatic stress disorder.

combined therapy Psychotherapy in which the patient is in both individual and group treatment with the same or two different

Telegram: @medical_k

www.konkur.in

therapists. In marriage therapy, it is the combination of married couples group therapy with either individual sessions with one spouse or conjoint sessions with the marital pair. *See also* co-therapy.

command automatism Condition closely associated with catalepsy in which suggestions are followed automatically.

command hallucination False perception of orders that a person may feel obliged to obey or unable to resist.

command negativism *See* negativism.

commitment Legal process by which a person is confined to a mental hospital, usually against their will.

common migraine *See* migraine.

communication disorder Term referring to a heterogeneous class of disorders resulting from impairment in the ability to receive, send, process, and comprehend concepts or verbal, nonverbal, and written symbolic systems. Communication disorders consist of language disorders, speech sound disorders, and social (pragmatic) communication disorder.

community *See* therapeutic community.

community mental health center Community or neighborhood mental health facility or a group of affiliated agencies that serve as a locus for the delivery of various services of community psychiatry. *See also* community psychiatry.

community psychiatry Psychiatry focusing on the detection, prevention, and early treatment of mental disorders and social deviance as they develop in the community, rather than as they are perceived and encountered at large centralized psychiatric facilities; particular emphasis is placed on the environmental factors that contribute to mental illness.

compensation Conscious or, usually, unconscious defense mechanism by which a person tries to make up (compensate) for an imagined or real physical or psychological deficiency.

compensation neurosis Neurosis induced by the desire for monetary compensation. It is believed that some persons, after sustaining an injury, develop neurotic symptoms in the hope of monetary gain.

Telegram: @medical_k

www.konkur.in

competence Ability to perform or accomplish an action or task that another person of similar background and training, or any human being, could reasonably be expected to perform; mental capacity.

competency to stand trial Ability to be tried in a court of law. A person is competent to stand trial when, at the time of the trial, they (1) understand the nature of the charge and the potential consequences of conviction and (2) is able to assist their attorney in their defense.

competition Literally, the struggle for the possession or use of limited goods, concrete or abstract. In psychiatry, a rivalry that may exist between persons in which gratification for one person largely precludes gratification for the other.

complementarity of interaction Concept of bipersonal and multipersonal psychology in which behavior is viewed as a response to stimulation, and interaction replaces the concept of reaction; each person in an interactive situation plays both a provocative role and a responsive role.

complementary role *See* role.

complex Group of interrelated ideas, mainly unconscious, that have a common emotional tone and strongly influence the person's attitudes and behavior; introduced by Jung, who called it a feeling-toned idea.

complex partial seizure Epilepsy characterized by recurrent behavioral disturbances. Complex hallucinations or illusions, frequently gustatory or olfactory, often herald the onset of the seizure, which typically involves a state of impaired consciousness resembling a dream (dreamy state) during which paramnestic phenomena, such as déjà vu and jamais vu, are experienced and the patient exhibits repetitive, automatic, or semipurposeful behavior; in rare instances, violent behavior may be prominent. Electroencephalography reveals a localized seizure focus in the temporal lobe. Also called psychomotor epilepsy; temporal lobe epilepsy.

complicated grief/bereavement *See* persistent complex bereavement disorder.

Telegram: @medical_k

www.konkur.in

compulsion Uncontrollable, repetitive, and unwanted urge to perform an act; serves as a defense against unacceptable ideas and desires, and failure to perform the act leads to overt anxiety. *See also* obsession.

compulsive personality Personality characterized by rigidity, overconscientiousness, extreme inhibition, inability to relax, and the performance of repetitive patterns of behavior.

computed tomography (CT) Radiologic imaging technique for presenting anatomical features from a cross-sectional plane of the body, generated by computer synthesis of x-ray transmission data obtained from many different directions through the given plane; gray and white matter are indistinguishable on CT scans.

conation That part of a person's mental life concerned with cravings, strivings, motivation, drives, and wishes as expressed through behavior or motor activity.

concordance In studies of twins, the degree of similarity between the two members of each pair with respect to the presence or absence of a particular trait. *Compare* discordance.

concrete operations *See* Piaget, Jean.

concrete thinking Thinking characterized by actual things and events and immediate experience, rather than by abstractions; seen in young children, in those who have lost or never developed the ability to generalize (as in certain organic mental disorder), and in schizophrenic persons. *Compare* abstract thinking.

concussion Immediate and transient impairment of brain function resulting from a head injury; usually, an alteration of consciousness is involved.

condensation Mental process in which one symbol stands for a number of components.

conditioned reinforcer *See* reinforcement.

conditioned response *See* conditioning.

conditioned stimulus *See* conditioning.

conditioning Procedure resulting in the acquisition or learning of more or less permanent changes in behavior. There are two main types of conditioning: **1.** Classical conditioning, in which a neutral stimulus is repeatedly paired with a stimulus (unconditioned

Telegram: @medical_k

www.konkur.in

stimulus) that naturally elicits a response (unconditioned response) until the neutral stimulus (conditioned stimulus) comes to elicit that response (now the conditioned response) by itself. Also called Pavlovian conditioning and respondent conditioning. **2.** Operant conditioning, a procedure developed by B. F. Skinner in which a spontaneously emitted behavior (operant behavior) is either rewarded (reinforced) or punished and, as a result, then occurs with a frequency that is either increased (in the case of reinforcement) or decreased (in the case of punishment). Also called instrumental conditioning. *See also* behavior therapy.

conditioning therapy *See* behavior therapy.

conditions not attributable to a mental disorder DSM category given to a person who may or may not have a mental disorder but who has a problem which may require intervention by a psychiatrist. Included are marital problem, occupational problem, phase of life or other life circumstance problem, malingering, complicated bereavement, antisocial behavior, academic problem, other interpersonal problem, other specified family circumstance, and noncompliance with medical treatment.

conduct disorder A diagnosis used in child psychiatry to refer to children who show antisocial behavior. Such behavior may occur as part of a group (group type), individually (solitary aggressive type), or both.

confabulation Unconscious filling of gaps in memory by imagining experiences or events that have no basis in fact, commonly seen in organic amnestic syndromes; should be differentiated from lying. *See also* paramnesia.

confidence interval Range of values with a specified probability of including the population mean with a specified level of confidence; typically associated with a certain probability level, for example, the 95% confidence interval has a 95% chance of including the population mean.

confidentiality Ethical principle by which the physician is bound to hold secret all information given to them by the patient. Certain states do not legally recognize confidentiality and can require the

Telegram: @medical_k

www.konkur.in

physician to divulge such information if needed in a legal proceeding. *See also* privilege.

conflict Mental struggle arising from the clash of opposing impulses, drives, or demands. *See also* extrapsychic conflict; intrapsychic conflict.

conflict-free area Part of one's personality or ego that is well integrated and does not cause any conflicts, symptoms, or displeasures.

confrontation Act of letting a person know where one stands in relationship to that person, what one is experiencing, and how one is perceived. Used in a spirit of deep involvement, this technique is a powerful tool for changing relationships; used as an attempt to destroy another person, it can be harmful. In group and individual therapies, the value of confrontation is likely to be determined by the therapist.

confusion Disturbance of consciousness manifested by a disordered orientation in relation to time, place, or person.

congenital Referring to conditions present at birth, including hereditary conditions and those resulting from prenatal development or the process of birth itself.

conjoint therapy Type of marriage therapy in which a therapist sees the partners together in joint sessions. Also called triadic or triangular therapy (since two patients and one therapist work together). *See also* quadrangular therapy.

conjugal paranoia Paranoia characterized by delusions of jealousy; with no evidence or little evidence, a spouse or lover becomes convinced that their partner is being unfaithful. Also called Othello syndrome.

conscience The part of the self that judges one's own values and performance; often used synonymously with superego.

conscious 1. One of three divisions of Freud's topographic theory of the mind (the others being the preconscious and the unconscious), referring to that portion of mental functioning within the realm of awareness at all times. **2.** More generally, the state having present knowledge of oneself, one's acts, and one's surroundings and thus

Telegram: @medical_k

www.konkur.in

a functioning sensorium. **3.** Denoting a state of awareness, with response to external stimuli.

consciousness State of awareness, with response to external stimuli. *See also* sensorium.

consensual validation Continuous comparison of the thoughts and feelings of group members toward one another that tends to modify and correct interpersonal distortions; introduced by Harry Stack Sullivan to refer to the dyadic therapeutic process between doctor and patient.

conservation According to Piaget, the crucial difference between preoperational and concrete operational thought, in which a child discovers which values remain invariant in the course of any kind of change or transformation.

conservator Legal guardian designated to take over and protect the interests of an individual.

constipation Inability to defecate or difficulty in defecating.

constitution One's intrinsic psychological or physical endowment. Broadly, it includes an aggregate of characteristics that have developed from the interaction of hereditary and environmental influences; more narrowly, it indicates characteristics that are purely hereditary or genetically determined.

constitutional types Categories of a person's traits based on physical and psychological characteristics (e.g., ectomorphic, endomorphic, mesomorphic).

constricted affect Reduction in intensity of feeling; tone less severe than that of blunted affect but clearly reduced.

constructional apraxia Inability to copy a drawing, such as a cube, clock, or pentagon, as a result of a brain lesion.

Consultation–liaison psychiatry Clinical psychiatry carried out in the medical or surgical wards of a general hospital; the psychiatrist collaborates closely with nonpsychiatric physicians in the total care of the patient.

contagion Force that operates in large groups or masses. When the level of psychological functioning has been lowered, some sudden upsurge of anxiety can spread through a group, accelerated by high degree of suggestibility, gradually mounting to panic, and the

Telegram: @medical_k

www.konkur.in

whole group may be simultaneously affected by a primitive emotional upheaval.

content thought disorder Disturbance in thinking in which a person exhibits delusions that may be multiple, fragmented, and bizarre.

continuous reinforcement A schedule of reinforcement in which reward is administered every time a response is emitted.

contract Explicit, bilateral commitment to a well-defined course of action; in group or individual therapy, the therapist–patient contract is to attain the treatment goal.

control group In an experimental design, the group in which a condition or factor being tested is deliberately omitted; for example, in a study measuring the effects of a new drug, the control group may be given a placebo instead of the drug. *Compare* experimental group.

controlled substance Drug that has the potential to be abused and is classified by the Drug Enforcement Administration (DEA) into one of five levels of control: I, high abuse potential and no accepted medical use (e.g., heroin); II, high abuse potential with medical use (e.g., amphetamine); III, moderate abuse potential (e.g., codeine); IV, low abuse potential, that is, preparations containing limited amounts of narcotic and nonnarcotic ingredients (e.g., cough medicines).

controlling Excessive attempt to manage or regulate events or objects in the environment to minimize anxiety and to resolve inner conflicts.

conversational catharsis Release of repressed or suppressed thoughts and feelings in group and individual psychotherapy as a result of verbal interchange. *See also* abreaction; catharsis.

conversion Unconscious defense mechanism by which the anxiety that stems from an intrapsychic conflict is converted and expressed in a symbolic somatic symptom; the hallmark of conversion disorder, but also seen in a variety of mental disorders.

conversion disorder Alternate term for functional neurologic symptom disorder.

conversion phenomena The development of symbolic physical symptoms and distortions involving the voluntary muscles or

Telegram: @medical_k

www.konkur.in

special sense organs; not under voluntary control and not explained by any physical disorder. Most common in conversion disorder, but also seen in a variety of mental disorders.

convulsion An involuntary, violent muscular contraction or spasm. *See also* clonic convulsion; tonic convulsion.

convulsive disorder *See* epilepsy.

convulsive therapy Psychiatric treatment involving administration of chemical substances or electric current to induce loss of consciousness or a convulsive reaction, to alter favorably the course of a mental disorder; for example, electroconvulsive therapy, insulin coma therapy.

cooperative therapy CO-THERAPY.

coping mechanism Unconscious or conscious way of dealing with stress.

coprolalia Involuntary use of vulgar or obscene language; observed in some cases of schizophrenia and in Tourette syndrome.

coprophagia Eating of filth or feces.

coprophilia Excessive interest in filth or feces. Sexual pleasure associated with feces is a perversion associated with fixations at the anal stage of psychosexual development.

coprophobia Abnormal fear of excreta.

copy-cat suicides Suicides that occur in persons who are geographically related; usually occurs among adolescents within a limited time period. *See also* cluster suicides.

correctional psychiatry Practice of psychiatry on persons incarcerated in jail or prison; presents special problems in relation to confidentiality and countertransference.

corrective emotional experience Re-exposure under favorable circumstances to an emotional situation that the patient could not handle in the past; as advocated by Franz Alexander, the therapist temporarily assumes a particular role to generate the experience and facilitate reality testing.

correlation Statistical index of the relationship among variables. The most common correlation coefficient is the Pearson Product

Telegram: @medical_k

www.konkur.in

Moment Correlation, an index of bivariate association that varies between >1.0 and 1.0. *See also* coefficient of correlation.

Cotard syndrome *See* nihilistic delusional disorder.

co-therapy Psychotherapy in which more than one therapist treat the individual patient or the group. Also called cooperative, dual, multiple, or three-cornered therapy. *See also* combined therapy.

counseling Form of guidance in which a trained person offers advice or education about specific problems in living, for example, marriage, child rearing, mourning.

counterphobia State in which a phobic person shows a preference for the very situation that is feared.

countertransference Conscious or unconscious emotional response of the therapist to the patient; determined by the therapist's inner needs, rather than by the patient's needs, and may reinforce the patient's earlier traumatic history if not checked by the therapist. *See also* transference.

couples therapy *See* family therapy; marriage therapy.

covert sensitization Method of reducing the frequency of behavior by associating it with the imagination of an unpleasant consequence.

CPA Canadian Psychiatric Association.

crack Freebase form of cocaine prepared by heating a mixture of cocaine hydrochloride, water, and baking soda, which is then dried into a solid and broken into small pieces (rocks); it is inexpensive, has a rapid onset of action, and is highly addictive.

creativity Ability to produce something new. Silvano Arieti described creativity as the tertiary process, a balanced combination of primary and secondary processes, in which materials from the id are used in the service of the ego.

cretinism Mental and physical retardation resulting from severe thyroid deficiency in infancy and childhood.

Creutzfeldt–Jakob disease (CJD) A rapidly progressive, invariably fatal disorder that occurs mainly in middle-aged or older adults. It initially manifests with fatigue, flu-like symptoms, and cognitive impairment; as it progresses, focal neurologic findings such as aphasia and apraxia occur. Psychiatric symptoms include anxiety,

Telegram: @medical_k

www.konkur.in

euphoria, depression, delusions, hallucinations, or marked personality changes. Progresses over months and leads to dementia, akinetic mutism, coma, and death.

Cri-du-chat High-pitched catlike cry characteristic of the syndrome of mental and physical retardation caused by partial deletion of chromosome 5. Also called cat's cry syndrome.

criminal responsibility Legal term meaning the ability to formulate a criminal intent at the time of an alleged crime. A person cannot be convicted of a crime if it can be proved that they lacked criminal responsibility by reason of insanity.

crisis In psychiatry, a distressing sense of psychological disequilibrium that has an acute onset and that causes impaired functioning in a variety of interpersonal and vocational areas.

crisis intervention Brief therapeutic approach used in emergency rooms of general or psychiatric hospitals that is ameliorative, rather than curative, of acute psychiatric emergencies; treatment factors often focus on environmental modification, although interpersonal and intrapsychic factors are also considered. *See also* hot line.

critical period Specific period of early development during which an organism acquires certain patterns of behavior as a result of internal or external clues. *See also* imprinting.

critical ratio In a statistical study involving 30 or more subjects, a ratio constructed to determine whether differences found between two items are larger than could be expected from chance alone.

cross-cultural psychiatry Comparative study of mental illness and health among various societies around the world.

cryptographia A private written language.

cryptolalia A private spoken language.

CT scan Computed tomography.

cult System of beliefs and rituals, especially involving devoted attachment to or extravagant admiration of a person or principle, based on dogma or religious teachings; devoted adherents to such a system are called cultists.

cultural anthropology *See* anthropology.

Telegram: @medical_k

www.konkur.in

cultural deprivation Restricted participation in the culture of the larger society.

cultural psychiatry Branch of psychiatry concerned with mental illness in relation to the cultural environment; symptoms regarded as psychopathologic in one cultural setting may be acceptable and normal in another.

culture shock Psychological response of a person who is suddenly thrust into an alien culture or has divided loyalties to two different cultures.

culture specific syndrome Disorder of behavior that occurs within or is limited to a specific culture; for example, amok, koro, latah.

cunnilingus Use of the mouth or tongue to stimulate the female genitalia.

Cushing syndrome Hyperadrenocorticism characterized by muscle wasting, obesity, osteoporosis, atrophy of the skin, and hypertension; emotional lability is common and frank psychoses are occasionally observed.

custody Term used to describe a parent's legal rights over a child; in cases of disputed custody, the child is awarded to the party who will best serve the interests of the child.

CVA Cerebral vascular accident.

cybernetics Norbert Wiener's term for the comparative study of computers and the human nervous system.

cybersex addiction A paraphilia characterized by dependence on the internet for sexual gratification (e.g., internet pornography, sex-chat rooms).

cyclazocine Narcotic antagonist that blocks the effects of morphine and heroin.

cycloplegia Paralysis of the muscles of accommodation in the eye; observed at times as an autonomic side effect (anticholinergic effect) of antipsychotic or antidepressant medication.

cyclothymia Mood disorder characterized by a nonpsychotic disturbance of at least 2 years length with numerous periods of both depressive and manic syndromes not severe enough to be classified as depressive or manic episodes.

Telegram: @medical_k

www.konkur.in

cyclothymic disorder Mood disorder characterized by a nonpsychotic disturbance of at least 2 years' length with numerous periods of both depressive and hypomanic syndromes that are not severe enough to be classified as depressive or hypomanic episodes.

cynophobia Abnormal fear of dogs.

D

Da Costa syndrome Chest pain, palpitations, and lightheadedness occurring as a somatic manifestation of pathologic anxiety. Also called neurocirculatory asthenia; soldier's heart.

day hospital Form of partial hospitalization in which a patient spends the day in the hospital and returns home at night. *Compare* night hospital; weekend hospital.

day residue In Sigmund Freud's dream theory, the content of the dream imagery that is derived from events of the previous day.

DEA Drug Enforcement Administration.

death instinct AGGRESSIVE DRIVE.

decathexis ACATHEXIS.

decision tree algorithm.

de Clérambault syndrome *See* erotomania.

decoding Technical term for the process of understanding spoken language.

decompensation Deterioration of psychic functioning due to a breakdown of defense mechanisms.

decomposition In psychiatry, the division of a person into separate personalities or identities, as seen in the paranoid schizophrenic person who splits the persecutor into separate entities.

deep brain stimulation A wired electrode with multiple stimulating sites that is surgically implanted into the brain chronically administers electrical stimulation. Use to treat tremor in Parkinson disease.

defense mechanism Unconscious process acting to relieve conflict and anxiety arising from one's impulses and drives.

Telegram: @medical_k

www.konkur.in

defensive emotion Strong feeling that serves as a screen for a less acceptable feeling, one that would cause a person to experience anxiety if it appeared. For example, expressing the emotion of anger is often more acceptable to a patient than expressing the fear that the anger covers up; in that instance, anger is defensive.

deficit In psychiatry, the absence of a function or capability that would normally be present, for example, judgment.

deinstitutionalization Discharge from the hospital to community, particularly of those chronically mentally ill patients who would otherwise be hospitalized for long periods of time.

déjà entendu Illusion that what one is hearing one has heard previously. *See also* paramnesia.

déjà pensè Condition in which a thought never entertained before is incorrectly regarded as a repetition of a previous thought.

déjà vu Illusion of visual recognition in which a new situation is incorrectly regarded as a repetition of a previous experience. *See also* paramnesia.

delayed ejaculation DSM-5 term for male orgasmic disorder.

delayed sleep phase circadian rhythm disorder A circadian rhythm sleep–wake disorder characterized by sleep–wake times that are later than conventional times; individuals with this disorder are referred to as “night owls.”

delirium Acute reversible organic mental disorder characterized by confusion and some impairment of consciousness; generally associated with emotional lability, hallucinations or illusions, and inappropriate, impulsive, irrational, or violent behavior.

delirium tremens (DTs) Acute and sometimes fatal reaction to withdrawal from alcohol, usually occurring 72 to 96 hours after the cessation of heavy drinking; distinctive characteristics are marked autonomic hyperactivity (tachycardia, fever, hyperhidrosis, dilated pupils), usually accompanied by tremulousness, hallucinations, illusions, and delusions. Called alcohol withdrawal delirium in DSM. *See also* formication.

delta sleep SLOW WAVE SLEEP.

Telegram: @medical_k

www.konkur.in

delta waves As measured by an electroencephalogram (EEG), brain waves that are less than 4 Hz, indicative of deep sleep.

delusion False belief that is firmly held, despite objective and obvious contradictory proof or evidence and despite the fact that other members of the culture do not share the belief. Types of delusion include: **bizarre delusion,** one that is patently absurd or fantastic; **delusion of control,** that a person's thoughts, feelings, or actions are not one's own but are being imposed by some external force; **delusion of grandeur (grandiose delusion),** exaggerated concept of one's importance, power, knowledge, or identity; **delusion of jealousy (delusion of infidelity),** that one's lover is unfaithful; **delusion of persecution,** that one is being attacked, harassed, cheated, or conspired against; **delusion of poverty,** that one is or will be without material possessions; **delusion of reference,** that events, objects, or the behavior of others have a particular and unusual meaning specifically for oneself; **encapsulated delusion,** one without significant effect on behavior; fragmentary delusion, poorly elaborated delusion, often one of many with no apparent interconnection; **nihilistic delusion, delusion of negation** (Cotard syndrome), that the world and everything related to it have ceased to exist; **paranoid delusion,** combined delusion of grandeur and persecution; **religious delusion,** one involving the Deity or theologic themes; **sexual delusion,** one centering on sexual identity, appearances, practices, or ideas; **somatic delusion,** pertaining to the functioning of one's body; **systematized delusion,** a group of elaborate delusions related to a single event or theme.

delusional depression Depressive disorder characterized by false, fixed ideas, that is, delusions; listed in DSM as major depression, severe, with psychotic features.

delusional (paranoid) disorder Psychotic disorder in which there are persistent delusions (e.g., erotomanic, grandiose, jealous, persecutory, somatic, mixed, and unspecified); symptoms of a major mood disorder are absent, and the delusions lack the bizarre quality often seen in schizophrenia.

Telegram: @medical_k

www.konkur.in

dementia Mental disorder characterized by general impairment in intellectual functioning, frequently characterized by failing memory, difficulty with calculations, distractibility, alterations in mood and affect, impairment in judgment and abstraction, reduced facility with language, and disturbance of orientation. Although generally irreversible because of underlying progressive, degenerative brain disease, dementia may be reversible if the cause can be treated. Called major neurocognitive disorder in DSM-5. *Compare* amentia.

dementia associated with alcoholism DSM term for alcoholic deterioration.

dementia of the Alzheimer type Term for a clinical disorder in an older adult patient characterized by a severe loss of intellectual function, for which no other cause is found, and that is progressive and insidious and marked by disorientation as to time, place, and person; senile onset is after age 65 (senile dementia); presenile onset is before age 65 (presenile dementia). Also called Alzheimer disease. *See also* Pick disease.

dementia praecox (precox) Obsolete term for schizophrenia.

demography Statistical study of populations, including births, marriages, mortality, health, geographic distribution, and population shifts.

demophobia Abnormal fear of crowds.

dendrite Projection from the nerve cell body, usually profusely branched and studded with small spikes (dendritic spines) that are the sites of synaptic connection; most dendrites receive neurotransmissions from an axon.

denial Defense mechanism in which the existence of unpleasant realities is disavowed; refers to a keeping out of conscious awareness any aspects of either internal or external reality that, if acknowledged, would produce anxiety.

dependence on therapy Pathologic need of a patient for therapy, created out of the belief that one cannot survive without it.

dependency State of reliance on another, as for security, love, protection, or mothering.

dependent personality disorder Personality disorder characterized by lack of self-confidence, a tendency to have others assume

Telegram: @medical_k

www.konkur.in

responsibility for significant areas of one's life, and a subordination of one's own needs and wishes to those of the others on whom one is dependent; solitude is extremely discomforting.

dependent variable In research methodology, those qualities that measure the influence of the independent variable or the outcome of the experiment; for example, measurement of a person's specific physiologic reactions to a drug. Also called outcome variable.

depersonalization Called depersonalization disorder in DSM-5, a disordered sensation of unreality concerning oneself, parts of oneself, or one's environment that occurs under extreme stress or fatigue. Seen also in schizophrenia and schizotypal disorder.

depersonalization disorder [Omit entry.]

depression Mental state characterized by feelings of sadness, loneliness, despair, low self-esteem, and self-reproach; accompanying signs include psychomotor retardation or at times agitation, withdrawal from interpersonal contact, and vegetative symptoms such as insomnia and anorexia. The term refers either to a mood that is so characterized or to a mood disorder.

depressive neurosis DYSTHYMIA.

depth psychology Psychology that focuses on unconscious processes, rather than conscious processes.

derailment Gradual or sudden deviation in train of thought without blocking; sometimes used synonymously with loosening of association.

derealization Called derealization disorder in DSM-5, disordered sensation of a changed reality or that one's surroundings have altered; also seen in schizophrenia.

dereism Mental activity that follows a totally subjective and idiosyncratic system of logic and fails to take the facts of reality or experience into consideration. *See also* autistic thinking.

dereistic thinking Mental activity not concordant with logic or experience.

descriptive psychiatry System of psychiatry focusing primarily on the study of observable symptoms and behavioral phenomena,

Telegram: @medical_k

www.konkur.in

rather than underlying psychodynamic processes; Emil Kraepelin's systematic description of mental illness was an early example. *See also* dynamic psychiatry.

descriptive statistics Methods used to summarize, organize, and describe observations; for example, the mean, standard deviation, and variance.

desensitization *See* systematic desensitization.

designer drug Any version of a regulated drug whose chemical structure has been modified so that it falls outside the restrictions placed on the regulated drug it imitates; usually a drug of abuse used to alter states of consciousness or to produce pleasurable feelings.

detachment A state of being in which the person is separated or divorced from emotional involvement with others, characterized by distant interpersonal relationships.

determinism Concept that nothing occurs by chance alone; instead, things result from specific causes or forces. This school of thought denies the notion of free will.

detoxification Any treatment aimed at the restoration of normal physiologic function after a disturbance by the use of some drug or chemical substance. *See also* cold turkey.

detumescence Subsiding of a penile erection; also used to describe the subsiding of genital engorgement in both sexes.

devaluation Defense mechanism in which a person attributes excessively negative qualities to self or others. Seen in depression and paranoid personality disorder.

developmental arithmetic disorder Academic skills disorder characterized by marked impairment in the development of arithmetic skills that interferes with academic achievement or other activities of daily living. Also called acalculia; Gerstmann–Straussler–Scheinker disease, congenital arithmetic disability; dyscalculia; arithmetic disorder.

developmental articulation disorder *See* speech sound disorder.

developmental coordination disorder Motor skills disorder of childhood with significant impairment in the development of fine or

Telegram: @medical_k

www.konkur.in

gross motor coordination that interferes with academic achievement or with activities of daily life.

developmental disorders Disorders originating in infancy and childhood that continue in adulthood and which interfere with the person's ability to function normally. In DSM, called neurodevelopmental disorders and include intellectual developmental disorder (formally known as mental retardation) and autistic spectrum disorders.

developmental expressive language disorder Language and speech disorder in which there is marked impairment in the development of expressive language; interferes with academic achievement or with activity of daily living that require the expression of verbal (or sign) language.

developmental expressive writing disorder Academic skills disorder characterized by marked impairment in the development of expressive writing skills; significantly interferes with academic achievement or with activities of daily living that require expressive writing skills.

developmental reading disorder Academic skills disorder characterized by omissions, distortions, and substitutions of words and by slow, halting reading; there is marked impairment in the development of words recognition skills and reading comprehension. Also called specific reading disability and developmental word blindness.

developmental receptive language disorder Language and speech disorder in which there is marked impairment in the development of language comprehension which significantly interferes with academic achievement or with activities of daily living that require comprehension of verbal (or sign) language.

developmental word blindness DEVELOPMENTAL READING DISORDER.

deviation Departure from the average or norm.

Dexamethasone Suppression Test (DST) Test used to confirm a diagnostic impression of major depression. The patient is given 1 mg of dexamethasone (a long-acting synthetic glucocorticoid) by mouth at 11 PM, and plasma cortisol is measured at 8 AM, 4 PM, and

Telegram: @medical_k

www.konkur.in

11 PM. Plasma cortisol above 5 μg/dL (nonsuppression) is considered abnormal, that is, positive; suppression of cortisol indicates that the hypothalamic–adrenal–pituitary axis is functioning properly.

***Diagnostic and Statistical Manual of Mental Disorders* (DSM)** Handbook for the classification of mental illnesses that is primarily descriptive and does not describe the theories or causes of disorders; first issued by the American Psychiatric Association in 1952 (DSM-I). The fourth edition (DSM-IV) was issued in 1994 and the text revision of fourth edition (DSM-IV-TR) was published in 2000. The DSM-5 was published in 2013 and its text revision (DSM-5-TR) was published in 2022.

dialectical behavior therapy (DBT) A form of therapy used for patients with borderline personality disorder and parasuicidal behavior that is eclectic using advice-giving, cognitive training, story-telling, and confrontation among many other techniques.

diathesis-stress paradigm In psychopathology, a view that abnormal behavior is a function of a series of stresses in predisposed individuals (due to hereditary, temperamental, and sociocultural factors).

differential diagnosis Determination of which of two or more diseases with similar symptoms is the one that afflicts the patient.

differential reinforcement Procedure in which desirable behavior is reinforced and problematic or less desirable behavior is extinguished or punished.

differentiation First of Margaret Mahler's four subphases of the separation–individuation process, occurring from ages 5 to 10 months, when the child is able to distinguish between self and other objects.

2,5-dimethoxy-4-methylamphetamine (DOM) Synthetic (derivative) drug with hallucinogenic properties. Also colloquially called STP.

dimethyltryptamine (DMT) Tryptamine congener that acts as a psychedelic capable of producing hallucinations, other disorders of perception, and altered moods and states of consciousness.

diminished libido Decreased sexual interest and drive.

Telegram: @medical_k

www.konkur.in

dipsomania An obsolete term that refers to the compulsion to drink alcoholic beverages.

disability Defined by the federal government as: “Inability to engage in any substantial gainful activity by reason of any medically determinable physical or mental impairment which can be expected to last or has lasted for a continuous period of not less than 12 full months.”

disconnection syndrome Group of neurologic disorders produced after interruption of connection fibers from the cerebrum to other centers of the nervous system.

discontinuation syndrome Signs and symptoms that occur when a person stops taking a drug either suddenly or gradually when the drug previously has caused physical or psychological dependence to occur. Also called abstinence syndrome; withdrawal syndrome.

discordance In studies of twins, the degree of dissimilarity between the two members of each pair with respect to the presence or absence of a particular trait. *Compare* concordance.

discriminant analysis Multivariate method for finding the relationship between a single discrete outcome and a linear combination of two or more predictors.

discrimination Process of distinguishing between different but often similar stimuli and reacting appropriately; more specifically, the occurrence of operant behavior in environments in which the behavior has been reinforced but not in those in which it has not been reinforced. *See also* discriminative stimulus.

discriminative stimulus Environmental event correlating with the operation of a certain reinforcement matrix, such that behavior that has been reinforced in the presence of the stimulus but not in its absence tends to occur only when the stimulus is present.

disinhibition 1. Removal of an inhibitory effect, as in the reduction of the inhibitory function of the cerebral cortex by alcohol. **2.** In psychiatry, a greater freedom to act in accordance with inner drives or feelings and with less regard for restraints dictated by cultural norms or one’s superego.

disinhibited social engagement disorder A disorder of markedly disturbed social relatedness in which a child approaches and

Telegram: @medical_k

www.konkur.in

interacts with unfamiliar adults in an overly familiar manner; presumed to result from grossly pathologic care-giving.

disintegration Psychic disorganization in which a person is unable to recognize reality and may develop delusions, hallucinations, or overwhelming anxiety and panic.

disorder of written expression A learning disorder characterized by writing skills that are significantly below the expected level for a child's age and intellectual capacity.

disorders of excessive somnolence Disorders characterized by excessive amounts of sleep or excessive daytime sleepiness. *See also* somnolence.

disorders of initiating and maintaining sleep Disorders characterized by inability to fall asleep or repeated awakening after failing asleep. *See also* insomnia disorder; dyssomnias.

disorganized schizophrenia Type of schizophrenia characterized by markedly disinhibited and aimless, nonconstructive behavior; no longer included in DSM-5.

disorientation Confusion; impairment of awareness of time, place, and person (the position of the self in relation to other persons); characteristic of cognitive disorders.

displacement Unconscious defense mechanism by which the emotional component of an unacceptable idea or object is transferred to a more acceptable one. Seen in phobias.

disposition Sum total of a person's inclinations as determined by their mood.

disruptive behavior disorders Disorders characterized by inattention, overagressiveness, delinquency, destructiveness, hostility, feelings of rejection, negativism, or impulsiveness. In DSM, they include attention-deficit hyperactivity disorder, conduct disorder, and oppositional defiant disorder.

disruptive mood dysregulation disorder A depressive disorder in individuals between 6 and 18 years of age that is characterized by chronic irritability, severe temper tantrums, and angry mood; a DSM-5 diagnosis.

dissociation Unconscious defense mechanism involving the segregation of any group of mental or behavioral processes from

Telegram: @medical_k

www.konkur.in

the rest of the person's psychic activity; may entail the separation of an idea from its accompanying emotional tone, as seen in dissociative and conversion disorders.

dissociation syndrome Functional inability of the brain to process information from one area to another; first described by neurologist Norman Geschwind. *See also* disconnection syndrome.

dissociative amnesia Disorder characterized by memory loss of important autobiographical information that is usually stressful or traumatic in nature.

dissociative disorders Mental disorders characterized by a sudden temporary alteration in consciousness, identity, or motor behavior. In DSM, they include dissociative amnesia, dissociative fugue, dissociative identity disorder, and depersonalization disorder. *See also* hysteria.

dissociative identity disorder Dissociative reaction in which a person has two or more distinct personalities, most of them knowing nothing of the others; a DSM-5 diagnosis. Previously called multiple personality disorder.

dissociative trance disorder Disorder characterized by temporary alteration in the state of consciousness or personal identity without replacement by an alternate identity; may occur during the course of a psychotic disorder or result from substance use. Not a DSM diagnosis.

distortion 1. Misrepresentation of reality. **2.** In psychoanalysis, the process of modifying unacceptable unconscious mental elements so that they are allowed to enter consciousness in a more acceptable but disguised form.

distractibility Inability to focus one's attention; the patient does not respond to the task at hand but attends to irrelevant phenomena in the environment.

distractible speech Pattern of speech in which a person changes subjects in response to nearby stimuli.

distributive analysis and synthesis Therapeutic application of Adolf Meyer's psychobiologic school of psychiatry; systematic investigations of patients' entire past experiences yield

Telegram: @medical_k

www.konkur.in

constructive syntheses of their assets and liabilities and lead to an effort to enable them to adapt to their environment.

disulfiram Drug used in the treatment of alcoholics. By altering the metabolism of alcohol, it produces unpleasant physical sensations that discourage the patient from further consumption of alcohol (trade name, Antabuse).

Dix, Dorothea Lynde (1802–1887) Former schoolteacher who became a prominent advocate for the indigent mentally ill. Her efforts helped create the first generation of American mental asylums in improving the humane treatment of the mentally ill.

dizygotic twins Twins (fraternal) who develop from two separately fertilized ova; in contrast, monozygotic (identical) twins develop from a single fertilized ovum.

DMT Dimethyltryptamine.

Doctor–patient relationship Human interchange that exists between the person who is sick and the person who is selected to heal because of training and experience.

DOES Disorders of excessive somnolence.

DOM 2,5-Dimethoxy-4-methylamphetamine.

dominance 1. Disposition to play a commanding, controlling, or prevailing role over others. **2.** In neurology, the control of language function by one side of the cerebral cortex. **3.** In genetics, the ability of a gene (dominant gene) to be expressed in the phenotype of the bearer to the exclusion of another gene (recessive gene) with which it is paired.

dopamine Biogenic amine (catecholamine) that inhibits prolactin; functional integrity of the dopaminergic system is impaired in depression and in Parkinson disease.

dopamine hypothesis Theory that there may be an excess of dopamine in the brains of persons with schizophrenia.

dopamine-receptor agonists Drugs that activate dopamine receptors in the absence of dopamine. Commonly used in the treatment of Parkinson disease.

dopamine-receptor antagonists (DRAs) Drugs that block the receptors for dopamine in the brain. Also known as first-generation

Telegram: @medical_k

www.konkur.in

or typical antipsychotics. *Compare* serotonin-dopamine antagonists.

double bind As formulated by Gregory Bateson, a situation involving the simultaneous communication of conflicting messages from one person to another, in which the response to either message is met with disapproval or rejection; believed to be a characteristic mode of interaction in some families with a schizophrenic member.

double-blind study Study in which, for example, one or more drugs and a placebo are compared in such a way that neither the patient nor the persons directly or indirectly involved in the study know which is being given to the patient; the drugs being investigated and the placebo are coded for identification.

double depression A mood disorder that occurs when the criteria for major depressive disorder and dysthymia are met simultaneously.

double personality *See* multiple personality disorder.

Down syndrome Syndrome of mental retardation associated with a variety of abnormalities caused by replication of chromosome 21 three times. Also called trisomy 21 syndrome. Formerly called mongolism.

DRA Dopamine-receptor antagonist.

Draw-A-Person (DAP) Test Easily administered test used with both children and adults, usually with the instructions, “I’d like you to draw a picture of a person; draw the best person you can.” A general assumption is that the drawing of a person represents the expression of the self or of the body in the environment.

drawing test Any of a variety of psychological tests in which the subject is asked to draw certain familiar objects, such as people, trees, and houses; attitudes and feelings are often revealed in the way the subject depicts those objects.

dread Massive or pervasive anxiety, usually related to a specific danger.

dream Mental activity during sleep in which thoughts, emotions, and images are experienced as though real; associated with rapid eye movement (REM) sleep. Dreams were regarded by Freud as

Telegram: @medical_k

www.konkur.in

providing an outlet for the discharge in disguised form of unconscious and often unacceptable impulses and wishes.

dream anxiety disorder *See* nightmare disorder.

dreamy state Altered state of consciousness, likened to a dream situation, that develops suddenly and from which the patient usually recovers within a few minutes; accompanied by visual, auditory, and olfactory hallucinations and most commonly associated with temporal lobe lesions.

drive Hypothetical construct used to explain motivated behavior: a basic urge that produces a state of psychic tension that motivates the person into action to alleviate the tension; currently preferred over Freud's term "instinct." *See also* aggressive drive; sexual drive.

drowsiness State of impaired awareness associated with a desire or inclination to sleep.

drug abuse Use of any drug, usually by self-administration, in a manner that deviates from approved social or medical patterns.

drug dependence Habituation or addiction to the use of a drug or chemical substance, with or without physical dependence; physical dependence indicates an altered physiologic state due to repeated administrations of a drug, the cessation of which results in the appearance of a withdrawal or abstinence syndrome characteristic for the particular drug which is called discontinuation syndrome.

Drug Enforcement Administration (DEA) Agency of the federal government that regulates distribution of controlled substances such as opioids, barbiturates, and other drugs of potential abuse.

drug holiday Limited period of time during which the administration of a psychoactive drug is discontinued in order to control dosage and side effects or to evaluate baseline behavior.

drug-induced parkinsonism PSEUDOPARKINSONISM.

drug interaction Effect that one drug has on the actions of one or more other drugs given at the same time; effects of either drug may be increased, diminished, or inactivated as a result of the interaction.

Telegram: @medical_k

www.konkur.in

drug levels Blood serum or plasma level of psychotropic drugs. *See also* pharmacokinetics.

drug therapy Use of chemical substances in the treatment of a disease or disorder. Also called chemotherapy.

drug tolerance *See* tolerance.

DSM *Diagnostic and Statistical Manual of Mental Disorders.*

DST Dexamethasone Suppression Test.

DTs Delirium tremens.

dual-sex therapy Specific form of psychotherapy developed by William Masters and Virginia Johnson in which treatment is focused on a particular sexual disorder. The crux of the program is the round-table session, in which both a male therapist and a female therapist are present with the patient couple; special exercises are prescribed for the couple, the overall goal being to diminish fears of sexual performance and to facilitate communication in sexual and nonsexual areas.

dual therapy CO-THERAPY.

dummy Uncommonly used term for placebo; for example, dummy drug.

Durham rule Federal court ruling in 1954 holding that "an accused is not criminally responsible if his unlawful act was the product of mental disease or mental defect." It has since been replaced by the American Law Institute formulation of insanity, which states that "a person is not responsible for criminal conduct if at the time of such conduct as a result of mental disease or defect he lacks substantial capacity either to appreciate the wrongfulness of his conduct or to conform his conduct to the requirements of law." *See also* M'Naghten rule.

dyad Pair of persons in an interactional situation, such as husband and wife, mother and father, co-therapists, or patient and therapist.

dyadic session Psychotherapeutic session involving only two persons, the therapist and the patient.

dynamic psychiatry System of psychiatry concerned with the mental mechanisms and emotional processes that govern and

Telegram: @medical_k

www.konkur.in

motivate human behavior, in contradistinction to descriptive psychiatry, which focuses on observable behavioral phenomena.

dynamic reasoning Franz Alexander's term for the formation of all the clinical evidence gained from free-associative anamnesis into a psychological reconstruction of the patient's development.

dynamics *See* psychodynamics.

dysarthria Impairment of articulation, the motor activity of shaping phonated sounds into speech.

dyscalculia Difficulty in performing calculations.

dysdiadochokinesis *See* adibdochokinesis.

dysgeusia Impairment of the sense of taste.

dysgraphia Difficulty in writing.

dyskinesia Any disturbance of movement, as in extrapyramidal dyskinesia.

dyslalia Faulty articulation due to structural abnormalities of the articulatory organs or impaired hearing.

dyslexia A specific learning disability syndrome involving an impairment of the ability to read; unrelated to the person's intelligence. *Compare* alexia.

dysmetria Impaired ability to gauge distance relative to bodily movements.

dysmnesia Impaired memory.

dysmorphophobia BODY DYSMORPHIC DISORDER.

dyspareunia Physical pain in sexual intercourse, usually emotionally caused and more commonly experienced by women; may also result from cystitis, urethritis, or other medical conditions. *See also* Genitopelvic pain/penetration disorder.

dysphagia Difficulty in swallowing.

dysphasia Difficulty in comprehending oral language (receptive dysphasia) or in trying to express verbal language (expressive dysphasia).

dysphonia Difficulty or pain in speaking.

dysphoria Feeling of unpleasantness or discomfort; a mood of general dissatisfaction, restlessness, depression, and anxiety.

dysphoric mood *See* dysphoria.

Telegram: @medical_k

www.konkur.in

dysprosody Loss of normal speech melody (prosody).

dyssocial behavior Former term for antisocial behavior.

dyssomnias Disturbances in the amount, quality, or timing of sleep. *See* insomnia disorder, hypersomnia disorder, and circadian rhythm disorder. *Compare* parasomnias.

dysthymia Mood disorder characterized by chronic depressed mood for at least 2 years that is not severe enough to meet criteria for major depressive episode. Also called depressive neurosis. *See also* depression.

dystonia Extrapyramidal motor disturbance consisting of slow, sustained contractions of the axial or appendicular musculature; one movement often predominates, leading to relatively sustained postural deviations; acute dystonic reactions (facial grimacing, torticollis) are occasionally seen with the initiation of antipsychotic drug therapy.

E

early ejaculation DSM-5 term for premature ejaculation.

eating disorders Disorders characterized by a marked disturbance in eating behavior; they include anorexia nervosa, bulimia nervosa, pica, and rumination disorder of infancy.

echolalia Repetition of another person's words or phrases, as observed in certain cases of schizophrenia, particularly the catatonic types. The behavior is considered by some authors to be an attempt by the patient to maintain a continuity of thought processes.

echopraxia Repetition of another person's movements, as observed in some cases of catatonic schizophrenia.

ecology Study of the mutual relationships between living things and their environment; includes such studies as the differential incidence of mental disorders in various populations and the distribution of crime and delinquency within a specified geographical area.

ecopsychiatry Study of genetic data and hypotheses about the role of social factors in mental disease.

Telegram: @medical_k

www.konkur.in

ecstasy **1.** State of rapturous delight. **2.** Slang term for methylenedioxymethamphetamine (MDMA).

ECT Electroconvulsive therapy.

ectomorphic Thin, characterized by a linear body musculature; one of Sheldon's constitutional types. *Compare* endomorphic; mesomorphic.

educable Capable of achieving a fourth- or fifth-grade academic level; describes the mildly mentally retarded (LQ of 50–55 to 70). *Compare* trainable.

educational psychology Area of psychology concerned with the application of psychological theories to teaching.

EEG Electroencephalogram.

ego One of the three components of the psychic apparatus in the Freudian structural framework, the others being the id and the superego. It occupies a position between the primal instincts and the demands of the outer world, therefore mediating between the person and external reality. In so doing, it performs the important functions of perceiving the needs of the self, both physical and psychological, the qualities and attitudes of the environment. It evaluates, coordinates, and integrates those perceptions so that internal demands can be adjusted to external requirements. It is also responsible for certain defensive functions to protect the person against the demands of the id and the superego. Although the ego has some conscious components, many of its operations are automatic; adaptation to reality is perhaps its most important function.

ego-alien Denoting aspects of a person's personality that are viewed as repugnant, unacceptable, or inconsistent with the rest of the personality. Also called ego-dystonic. *Compare* ego-syntonic.

ego analysis Psychoanalytic study of the manner in which the ego operates, especially in relation to intrapsychic conflicts. *See also* ego psychology.

ego boundaries Concept introduced by Paul Federn that refers to the ability of the intact ego to differentiate the real from the unreal. Ego boundaries prevent repressed unconscious material from overwhelming the ego; when that happens, a person experiences

Telegram: @medical_k

www.konkur.in

depersonalization and derealization. Boundaries are said to be weakened in schizophrenia and dissociative states.

egocentric Self-centered; selfishly preoccupied with one's own needs; lacking interest in others.

ego-coping skill Adaptive method or capacity developed by a person to deal with or overcome a psychological or social problem.

ego defense Defense mechanism to protect the person against the demands of the id and the superego.

ego-dystonic EGO-ALIEN.

ego-dystonic homosexuality Controversial term for the purported state of a person who has unwanted and distressful homosexual arousal and wishes to acquire or increase heterosexual arousal. Removed from DSM for the DSM-III-R revision of the book.

ego ideal Part of the personality representing a fusion of the ego and the superego; feelings of self-satisfaction are experienced when the person's thoughts, behavior, or impulses coincide with an internalized goal or ideal.

egomania Morbid self-preoccupation or self-centeredness. *See also* narcissism.

ego model Person after whom one patterns the ego.

ego psychology Study of the operations of ego in regard to control and regulation of instinctual drives, the relation to reality, and the development of object relations. *See also* ego analysis.

ego strength Degree to which the ego's functions, for example, perception, thinking, and speaking, are maintained.

ego-syntonic Denoting aspects of a person's personality that are viewed as acceptable and consistent with their total personality. *Compare* ego-alien.

eidetic image Unusually vivid or exact mental image seen or imagined event; may include color or movement.

ejaculation Expulsion of semen and seminal fluid from the urethra, as in male orgasm.

ejaculatory incompetence INHIBITED MALE ORGASM.

elaboration Unconscious process of embellishing the symbolic content of a dream.

Telegram: @medical_k

www.konkur.in

elation Affect consisting of feelings of joy, euphoria, triumph, intense self-satisfaction, or optimism.

elective mutism Childhood mental disorder in which a child who is able and willing to speak to selected persons persistently refuses to speak in other social or school situations.

Electra complex Obsolete and controversial term for a supposed female analog of the Oedipus complex in the male; infrequently used term to describe unresolved developmental conflicts influencing a woman's relationships with men.

electroconvulsive therapy (ECT) Convulsive therapy, usually for depression, that involves the application of electric current to the brain for a fraction of a second through scalp electrodes to induce a convulsive reaction and unconsciousness.

electroencephalogram (EEG) Recording of the brain's electrical potentials obtained by scalp electrodes.

electromyogram (EMG) Recording of the electrical activity of muscles at specific sites.

electroshock therapy (EST) *See* electroconvulsive therapy.

electrostimulation In aversion therapy, a negative conditioning technique consisting of (usually painful) electric shocks.

elevated mood Air of confidence and enjoyment; a mood more cheerful than normal but not necessarily pathologic.

elimination disorders Inability as a result of physiologic or psychological immaturity to maintain bowel control (functional encopresis) or bladder control (functional enuresis).

elopement Escape; absenting oneself from a mental hospital without permission.

emancipated minor Legal term for a minor who exercises general control over their life and hence has the legal rights of an adult.

EMG Electromyogram.

emotion Complex feeling state with psychic, somatic, and behavioral components; external manifestation of emotion is affect.

emotional deprivation Relative lack of environmental or interpersonal experiences during the early developmental years. *See also* sensory deprivation.

Telegram: @medical_k

www.konkur.in

emotional disorder Lay term for a mental illness or mental disorder; in common usage it does not specifically imply a mood disorder or schizophrenia.

emotional disturbance Emotional disorder or illness. *See also* mental disorder.

emotional illness General term for a behavioral or psychological syndrome or pattern associated with distress, disability, or increased risk of suffering.

emotional insight Deeper level of understanding or awareness that is more likely to lead to positive changes in personality and behavior.

emotional lability Excessive emotional responsiveness characterized by unstable and rapidly changing emotions.

emotional support Encouragement, hope, and inspiration given to one person by another.

empathy Intellectual and emotional awareness and understanding of another person's state of mind, involving the projection of oneself into another person's frame of reference; an important ability in a successful therapist or a helpful group member. *Compare* sympathy.

empty nest syndrome Depression that can occur in men and women when their youngest child is about to leave or has left home.

encapsulated delusion Delusion that has no significant effect on behavior.

encephalitis Inflammation of the brain.

encephalopathy Any disease of the brain.

encopresis Repeated passage of feces in inappropriate places, such as clothing or bed; diagnosis not made until after age 4.

encounter group Form of sensitivity training, introduced and developed by Jacob Moreno in 1914, that emphasizes the experiencing of individual relationships within the group and that minimizes intellectual and didactic input; the group focuses on the present, rather than concerning itself with the past or outside problems of its members. *See also* sensitivity training group.

Telegram: @medical_k

www.konkur.in

endemic Belonging, native, restricted, or peculiar to a particular people, country, locality, or region.

endocrine disorder Dysfunction of any of the endocrine glands, frequently with psychiatric manifestations.

endogamy Marriage within a specific group. *Compare* exogamy.

endogenous depression Obsolete term for a type of depression that originates within the person and is not related to external events, with a cause that is biologic or somatic. Also called nonreactive depression.

endomorphic Obese, with prominence of the abdomen; one of Sheldon's constitutional types. *Compare* ectomorphic; mesomorphic.

endorphin Any of several endogenous opioid peptides (α-, β-, or γ-endorphin) found in highest concentrations in the pituitary gland and which has analgesic and behavioral effects in animals. *See also* enkephalin.

engram Memory trace, the neurophysiologic substrate of memory.

enkephalin Endogenous opioid peptide released by β-endorphin that has analgesic properties and many of the actions of morphine.

entomophobia Fear of insects.

enuresis Repeated incontinence of urine in inappropriate places, such as clothing or bed; diagnosis not made until after age 5.

epidemiology In psychiatry, the study of the incidence, prevalence, control, and distribution of mental disorders within a particular population.

epigenesas Term introduced by Erik Erikson to refer to the stages of ego and social development.

epilepsy Neurologic disorder resulting from a sudden, excessive, disorderly discharge of neurons in either a structurally normal or a diseased cerebral cortex; characterized by paroxysmal recurrence of short-lived disturbances of consciousness, involuntary convulsive muscle movements, psychic or sensory disturbances, or some combination thereof. Termed idiopathic epilepsy when there is no identifiable organic cause. For types of epilepsy, see the specific term.

Telegram: @medical_k

www.konkur.in

epileptic dementia Epilepsy accompanied by progressive mental and intellectual impairment; some believe that the circulatory disturbances during epileptic attacks cause nerve cell degeneration and lead to dementia.

epileptic equivalent Epileptic phenomenon that is neither grand mal nor petit mal. *See also* complex partial seizure.

epileptic personality EXPLOSIVE PERSONALITY.

epinephrine Sympathomimetic catecholamine formed from norepinephrine and the major hormone secreted by the adrenal medulla; its release during states of fear or anxiety produces many of the physiologic changes associated with those emotions. Also called adrenaline.

episodic Denoting an illness in which there are sustained disturbances clearly distinguished from previous functioning.

epistemology Study or theory of the nature and grounds of knowledge, especially with reference to its limits and validity.

erectile dysfunction MALE ERECTILE DISORDER.

eremophobia Abnormal fear of being by oneself.

ergasia Adolf Meyer's term for a person's total activity, as opposed to the functioning of parts of the whole.

Erikson, Erik (1902–1990) Psychoanalyst noted for his theory of ego development and psychosocial development, which he conceptualized in terms of social adaptation as it relates to Sigmund Freud's formulations.

erogenous zone Any area of the body, principally the genitals, anus, and mouth, capable of being stimulated sexually.

eros SEXUAL DRIVE.

erotic Invested with sexual feeling.

erotomania Delusional conviction that another person is in love with them; typically the object of the delusion is of higher rank or status. Also referred to as de Clérambault syndrome or psychose passionelle.

erythrophobia Abnormal fear of blushing.

escape learning *See* avoidance and escape learning.

ESP Extrasensory perception.

Telegram: @medical_k

www.konkur.in

EST Electroshock therapy.

estrogen Hormone produced mainly by the ovaries and responsible for the development of the female reproductive organs and secondary sex characteristics: for example, estradiol, estriol, estrone. *Compare* androgen.

ethnocentrism Conviction that one's own group is superior to other groups; impairs one's ability to evaluate members of another group realistically or to communicate with them on an open, equal, and person-to-person basis.

ethnology Branch of anthropology dealing with the division of mankind into races and their origin, history, customs, and institutions.

ethology Study of animal behavior; often applied to the understanding of human behavior.

etiology Study of the causes of disease and their mode of operation.

euergasia Word used by Adolf Meyer to mean normal mental functioning.

euphoria Exaggerated feeling of well-being that is inappropriate to apparent events; may be induced by drugs such as opiates, amphetamines, and alcohol.

euphoric mood *See* euphoria.

euphorohallucinogen Substance capable of producing euphoric hallucinations.

euthymia Normal range of mood, implying absence of depressed or elevated mood.

euthymic Denoting a normal mood.

evasion Act of not facing up to or of strategically eluding something; consists of suppressing an idea that is next in a thought series and replacing it with another idea closely related to it. Also called paralogia; perverted logic.

event-related euphoria Morbid or abnormal sense of well-being associated with a specific situation or event.

evoked potential (EP) Following repetitive stimuli, the characteristic EEG waveform that remains after averaging out most of the brain electrical activity; clinically useful in evaluating the functional integrity of the somatosensory or special sensory pathways.

Telegram: @medical_k

www.konkur.in

exaltation Feeling of intense elation and grandeur.

excited Agitated, purposeless motor activity uninfluenced by external stimuli.

excitement phase Stage in the human sexual response after sexual stimulation, as described by Masters and Johnson, characterized by an objective sense of pleasure and accompanying physical changes (penile erection and vaginal lubrication).

excitoxicity Increased simulation of neurons due to injury or chemical neurotransmitters that cause cell death.

excoriation disorder Disorder characterized by compulsive picking of one's own skin, resulting in lesions, despite repeated efforts to decrease or stop picking. Also called skin-picking disorder.

executive ego function Part of the ego that helps maintain or manage one's relationship to and sense of reality.

exhaustion state Final stage of the body's response to major stress, as in the general adaptation syndrome.

exhibitionism Paraphilia in which a man exposes his genitals to females in a socially inappropriate fashion; rarely occurs in women. Also called exhibitionistic disorder.

existentialism Philosophic theory that questions the purpose and nature of existence itself; a fundamental focus is on the meaning of life in face of death and the end of one's personal existence.

existential psychotherapy Type of therapy, based on existential philosophy, that puts the emphasis on here-and-now interaction and on feeling experiences, rather than on rational thinking; little attention is given to patient resistances, and the therapist is involved on the same level and to the same degree as the patient. *See also* phenomenology.

exogamy Marriage outside of a specific group; in a biologic sense, the union of gametes of unrelated parents. *Compare* endogamy.

exogenous In psychiatry, denoting disordered behavior produced by forces outside of the body, as in adjustment disorder.

exorcism Magical practice in which mystical incantations are invoked to remove demons that are alleged to have entered the mind.

Telegram: @medical_k

www.konkur.in

expansive mood Expression of feelings without restraint, frequently with an overestimation of their significance or importance. Seen in mania and grandiose delusional disorder.

experiencing Feeling emotions and sensations, as opposed to thinking; being involved in what is happening, rather than standing back at a distance and theorizing.

experimental bias Error in construction of an experiment or study that favors one outcome over another.

experimental design Manner in which an experiment is logically organized in order to maximize the probability of obtaining real effects.

experimental group In an experimental design, the group that is exposed to the experimental manipulation under study. Compare control group.

experimental neurosis Abnormal behavior produced in a laboratory setting; used by Ivan Pavlov to describe symptoms of extreme and persistent agitation that he produced in dogs.

expert witness Legal concept that refers to the physician in the courtroom who is deemed sufficiently knowledgeable in a field to draw informed conclusions from data, for example, that a patient meets the required criteria for commitment or for an insanity defense.

explosive personality Personality type characterized by rigidity, egocentricity, selfishness, religiosity, seclusiveness, explosive outbursts of emotion, and extreme rage reactions when frustrated; enuresis is common.

expressive aphasia Disturbance of speech in which understanding remains, but ability to speak is grossly impaired; halting, laborious, and inaccurate speech. Also known as Broca's, nonfluent, and motor aphasias.

expressive dysphasia Difficulty in expressing verbal language; the ability to understand language is intact.

extended-family therapy Type of family therapy that involves family members, beyond the nuclear family, who are closely associated with it and affect it. *See also* social network therapy.

Telegram: @medical_k

www.konkur.in

externalization More general term than projection that refers to the tendency to perceive in the external world and in external objects elements of one's own personality, including instinctual impulses, conflicts, moods, attitudes, and styles of thinking.

external validity Statistical term that refers to how well a test measures what it purports to measure and identifies what it is supposed to identify.

extinction Process by which an operant behavior occurs less frequently when its performance is no longer reinforced.

extrapsychic conflict Conflict that arises between a person and their environment. Also called interpersonal conflict. *Compare* intrapsychic conflict.

extrapyramidal dyskinesia Movement disorder related to dysfunction of the extrapyramidal motor system; signs include a variety of involuntary movements and postures, muscular rigidity, tremor, and gait disturbance, as seen in Parkinson disease, chorea, athetosis, and hemiballismus. Extrapyramidal dyskinetic syndromes may occur as a side effect of antipsychotic drugs; such drug-induced extrapyramidal effects include a parkinsonian syndrome, akathisia, acute dystonic reactions, and tardive dyskinesia.

extrapyramidal effect Bizarre, involuntary motor movement; a central nervous system side effect sometimes produced by antipsychotic drugs. *See also* extrapyramidal dyskinesia.

extrapyramidal motor system Polysynaptic neural pathways involving the basal ganglia and related subcortical nuclei that influence motor behavior.

extrapyramidal syndrome Abnormalities of movement related to injury of motor pathways other than the pyramidal tract; for example, parkinsonism, akathisia, dystonia, tardive dyskinesia.

extrasensory perception (ESP) Experiencing an external event by means other than the five senses, as by telepathy or clairvoyance.

extroversion, extraversion State of one's energies being directed outside oneself. *Compare* introversion.

Telegram: @medical_k

www.konkur.in

F

factitious disorder Mental disorder characterized by the voluntary production of false or unreal physical or psychological symptoms; unlike malingering, there is no apparent goal or obvious benefit. Also called Munchausen syndrome. *Compare* somatic symptom disorder; somatoform disorders.

factitious disorder by proxy A disorder in which one person deceitfully creates false signs or symptoms of illness in another person who is under their care; most commonly this condition involves a mother presenting her child as ill. In some cases actual injury or illness may be inflicted on the dependent person. Diagnosed as "factitious disorder imposed on another" in DSM-5.

factitious disorder imposed on another *See* factitious disorder by proxy.

factor analysis Data reduction technique used to reduce a large number of variables to a smaller number of linear combinations of variables.

failure to thrive Delay in physical growth in infants and young children; often accompanied by impaired social and motor development; commonly associated with parental deprivation or neglect when no medical illness is detected. *See* reactive attachment disorder.

false memory A person's recollection and belief of an event that did not actually occur. In false memory syndrome, persons erroneously believe that they sustained an emotional or physical (e.g., sexual) trauma early in life.

false negative Diagnosis of a disorder as being absent in a person (tested negative) when in fact it is present.

false positive Diagnosis of a disorder as being present in a person (tested positive) when in fact it is not present.

falsifiable hypothesis Testable hypothesis that can be confirmed or disconfirmed.

family neurosis Mental disorder in which a person's psychopathology is unconsciously interrelated with that of other members of the family.

Telegram: @medical_k

www.konkur.in

family therapy Treatment of more than one member of a family in the same session; family relationships and processes are explored as potential causes of mental disorder in one or more of the family members. *See also* extended-family therapy.

fantasy Daydream; fabricated mental picture of a situation or chain of events. A form of thinking dominated by unconscious material and primary processes that seeks wish fulfillment and immediate solutions to conflicts; may serve as the matrix for creativity or for neurotic distortions of reality.

fatal familial insomnia An inherited prion disease characterized by insomnia and autonomic nervous system dysfunction (e.g., fever, sweating, tachycardia).

father surrogate, father substitute In psychoanalysis, a person onto whom the patient projects their father image and to whom they respond unconsciously in an inappropriate and unrealistic manner, with the feelings and attitudes held toward the real father.

fatigue A feeling of weariness, sleepiness, or irritability after a period of mental or bodily activity. Seen in depression, anxiety, neurasthenia, and somatoform disorders.

fausse reconnaissance False recognition, a feature of paramnesia. Can occur in delusional disorders.

faux de mieux Literally, “for want of anything better,” connoting in psychiatry a person choosing a homosexual relationship when no partner of the opposite sex is available.

FDA Food and Drug Administration.

fear Unpleasurable emotional state consisting of psychophysiologic changes in response to a realistic threat or danger. *Compare* anxiety.

feeble-mindedness Obsolete term for mental retardation, which is also called intellectual developmental disorder.

feedback 1. In a given system, the return, as input, of some form of information regarding the output; used as a regulatory mechanism. **2.** In psychiatry, the verbally or otherwise expressed response to a person’s behavior by another person or a group.

feeding disorder of infancy or childhood *See* avoidant/restrictive food intake disorder.

Telegram: @medical_k

www.konkur.in

fellatio Use of the mouth or tongue to stimulate the male genitalia.

femaleness Anatomic and physiologic features relating to female procreative functions.

female orgasmic disorder Disorder characterized by a woman's inability to achieve orgasm by coitus or masturbation.

feminine identity Inner sense of gender affiliation with females. *Compare* masculine identity.

Ferenczi, Sandor (1873–1933) Hungarian psychoanalyst who was one of Sigmund Freud's early followers and a brilliant contributor to all aspects of psychoanalysis; he came to favor more active and personal techniques than Freud's, to the point that his adherence to psychoanalysis during his last years was questioned.

fetal alcohol syndrome A syndrome that occurs when mothers consume alcohol during pregnancy resulting in fetuses born with birth defects, CNS dysfunction, and intellectual disability.

fetishism Paraphilia in which sexual excitement and gratification are achieved by substituting an inanimate object (such as a shoe, piece of underwear, or other article of clothing) for a human love object. Also called fetishistic disorder.

fibromyalgia A chronic pain disorder characterized by pain and stiffness of the soft tissues (e.g., muscles, ligaments, tendons).

field theory Conceptual approach to the study of personality formulated by Kurt Lewin that focuses on an operational analysis of the causal determinants of human behavior; it is expressed in geometric and mathematical terms borrowed from physics in an attempt to provide a framework suitable to the scientific study of human behavior. The person and their environment together constitute the life space, a complex field of forces acting on the personality and determining behavior.

finger agnosia Agnosia characterized by inability to name fingers; suggests a lesion in the dominant parietal lobe.

fixation 1. Arrest of psychosexual development at any stage before complete maturation. 2. Close and paralyzing attachment to another person, such as one's mother or father.

fixed-interval schedule *See* schedule of reinforcement.

fixed-ratio schedule *See* schedule of reinforcement.

Telegram: @medical_k

www.konkur.in

flagellantism, flagellation Process by which sexual partners are aroused and gratified by whipping or being whipped.

flashback hallucinosis Spontaneous recurrence, after a drug-free period, of hallucinations similar to those experienced during an acute toxic episode; often associated with repeated ingestions of LSD. Hallucinations are predominantly visual and may last for months after the last use of a drug.

flat affect Absence or near absence of any signs of affective expression.

flexibilitas cerea CATALEPSY.

flight of ideas Rapid succession of fragmentary thoughts or speech in which content changes abruptly and speech may be incoherent, as seen in mania.

floccillation Aimless plucking or picking, usually at bed-clothes or clothing, commonly seen in senile psychosis and delirium.

flooding Behavior therapy designed to extinguish phobias or anxiety through the presentation of the aversive stimuli in intense forms until the emotional responses cease. Also called implosion therapy.

fluent aphasia Aphasia characterized by inability to understand the spoken word; fluent but incoherent speech is present. Also called Wernicke aphasia, sensory aphasia, and receptive aphasia.

folie à deux Mental illness shared by two persons, usually involving a common delusional system; if it involves three persons, it is referred to as folie à trios, and so forth. *See* shared psychotic disorder.

follow-up examination To the physician, the aftercare and monitoring of patients' responses to treatment and the state of their physical health or mental status.

Food and Drug Administration (FDA) Federal agency that standards for the sale and use of drugs, food substances, and cosmetics.

forensic psychiatry Branch of psychiatry concerned with the aspects of mental illness.

Telegram: @medical_k

www.konkur.in

foreplay Sexual play that precedes sexual intercourse. Also called forepleasure.

forepleasure FOREPLAY.

formal operations Jean Piaget's label for completely developed logical thinking capacities. *See also* Piaget, Jean.

formal thought disorder Disturbance in the form of thought rather than the content of thought; thinking characterized by loosened associations, neologisms, and illogical constructs; thought process is disordered, and the person is defined as psychotic. Characteristic of schizophrenia.

formication Tactile hallucination involving the sensation that tiny insects are crawling over the skin; most commonly encountered in cocaine addiction and delirium tremens.

for-profit hospital Investor-owned or proprietary hospital; hospital owned and operated by physicians or corporations that earns a profit for its investors.

fragile X syndrome A syndrome resulting from a mutation on the X chromosome. Includes severe intellectual disability, a large head, long face, prominent ears, and, in males, large testicles.

fragmentary delusion Poorly elaborated delusion, often one of many with no apparent interconnection.

fraternal twins DIZYGOTIC TWINS.

free association Investigative psychoanalytic technique devised by Freud in which the patient seeks to verbalize without reservation or censorship the passing contents of their mind.

freebase Cocaine hydrochloride mixed with ammonia and an alkali solution, and then extracted with a solvent into a crystalline form. *See also* crack.

free-floating anxiety Severe, pervasive, generalized anxiety that is not attached to any particular idea, object, or event; observed particularly in anxiety disorders, although it may be seen in some cases of schizophrenia.

Fregoli syndrome The delusional belief that a known person is an imposter who assumes different appearances or disguises.

Telegram: @medical_k

www.konkur.in

frequency Number of cases having a certain score or characteristic; relative frequency measures the number of persons in a specific group (e.g., sex or age) who have a disorder.

frequency distribution Statistical description of raw data in terms of the number of cases that fall into each interval within a set of data; often presented graphically in the form of a frequency histogram or frequency polygram.

Freud, Anna (1895–1982) Daughter of Sigmund Freud noted for her contributions to the developmental theory of psychoanalysis and the mechanisms of defense.

Freud, Sigmund (1856–1939) Austrian psychiatrist and the founder of psychoanalysis. With Josef Breuer, he explored the potentialities of cathartic therapy and then went on to develop the analytic technique and such fundamental concepts as mental sublimation, as well as superego, ego, and id formation and their applications throughout all spheres of human behavior. Among his publications are *The Interpretation of Dreams* (1899). *Studies on Hysteria* (1895, with Breuer), and *Three Essays on the Theory of Sexuality* (1905).

frigidity Outdated term referring, in the female, to lack of sexual response or feeling, ranging from complete lack of arousal to incomplete climax.

frontal lobe syndrome Mental disorder characterized by a marked change in personality, with development of certain relatively characteristic patterns of relating to the environment that have been associated with lesions of the frontal lobes; such patterns include emotional lability, impairment in impulse control and social judgment, and marked apathy and indifference.

frontotemporal dementia Rare form of presenile dementia caused by cerebral atrophy predominantly in the frontotemporal regions of the brain; early stages are characterized by personality and behavior changes. The following progressive cognitive deterioration is indistinguishable clinically from the far more common Alzheimer disease, in which the cerebral atrophy is diffuse. Also called Pick disease. *See also* dementia of the Alzheimer type.

Telegram: @medical_k

www.konkur.in

frottage, frotteurism Sexual aberration in which arousal results from rubbing up against someone, usually without specific genital contact, as in a crowd; a person so afflicted is a frotteur. Also called frotteuristic disorder.

frustration Result of the thwarting of any goal-directed behavior; the ability to tolerate frustration and delay gratification is considered a sign of maturity and good ego strength.

fugue Called dissociative fugue in DSM-5, a subtype of dissociative amnesia characterized by a period of almost complete amnesia, during which a person actually flees from an immediate life situation and begins a different life pattern; apart from the amnesia, mental faculties and skills are usually unimpaired. *See also* psychogenic amnesia.

fulfillment Satisfaction of a need or wish.

functional Denoting changes in functioning not attributable to known organic alterations.

functional disorder Disorder that is not caused by an anatomical defect or any other identifiable or demonstrable cause. *Compare* organic disorder.

functional neurologic disorder *See* conversion disorder.

functional neurologic symptom disorder Mental disorder in which the patient experiences an involuntary limitation or alteration of physical function that is an expression of a psychological conflict or need, not of a physical disorder. Previously called conversion disorder in DSM-IV. *See also* hysteria.

functional speech disorder DEVELOPMENTAL ARTICULATION DISORDER.

fusion In psychoanalysis, the joining together of instincts which enables the person to function normally.

G

GABA γ-(gamma) aminobutyric acid.

GAF Scale GLOBAL ASSESSMENT OF FUNCTIONING SCALE.

galactorrhea Abnormal discharge of milk from the breast; may be a result of the endocrine influence of phenothiazine drugs.

Telegram: @medical_k

www.konkur.in

galvanic skin response (GSR) Measurable change in the electrical resistance of the skin, used as an index of emotional response.

gambling disorder DSM-5 disorder characterized by persistent and recurrent maladaptive gambling that leads to economic problems and disturbances in personal, social, and occupational functioning. Also called pathologic gambling.

γ-(gamma) aminobutyric acid (GABA) Inhibitory amino acid neurotransmitter synthesized by the actions of glutamic acid decarboxylase; GABA receptors are located at postsynaptic sites.

gamophobia Abnormal fear of marriage.

Ganser syndrome Rare atypical disorder, seen in prisoners, characterized by a giving of approximate answers to questions and of talking past the point; to be distinguished from factitious disorder and malingering.

gargoylism Old name for the gargoyle-like facies and dwarfism seen in Hunter and Hurler syndromes: metabolic disorders of mucopolysaccharide metabolism characterized by severe developmental skeletal deformities and mental retardation.

GAS General adaptation syndrome.

gatekeeper In community psychiatry, a person who evaluates the degree of psychological or environmental stress sufficient to enable a patient to gain access to the mental health care system.

gateway drugs Substances of abuse, such as alcohol and marijuana, which provide major portals of entry into abuse of other drugs; considered particularly dangerous because they are believed by so many to be relatively harmless.

Gault decision U.S. Supreme Court 1967 decision mandating fair and accurate fact-finding procedures for juveniles when serious punishment could be inflicted should they be found guilty; rights guaranteed the juvenile include the right to notification of the specific charges, the right to counsel, the right against self-incrimination, and the right to confront and cross-examine the accusers.

gay 1. Preferred term for a homosexual, especially male. **2.** Denoting a homosexual or the lifestyle thereof.

Telegram: @medical_k

www.konkur.in

gegenhalten Neurologic term (from the German) for involuntary active resistance to passive movement of the extremities, as may occur in cerebral cortical disorders.

gender dysphoria The DSM-5 term for gender identity disorder. May first appear in childhood, adolescence, or adulthood.

gender identity Culturally determined sets of attitudes, behavior patterns, and physical attributes usually associated with masculinity and femininity. *Compare* sexual identity.

gender identity disorder Psychosexual disorder in which a person feels discomfort with and inappropriateness of their biologic sex, with a marked preference for the clothing and activities of the opposite sex and/or repudiation of the sex organs. Also called gender dysphoria. *See also* transsexualism.

gender role Public declaration of gender; the image of maleness or femaleness that is communicated to others which may or may not coincide with gender identity.

general adaptation syndrome (GAS) Hans Selye's term for the responses of the body to major stress, passing through the alarm reaction, resistance and, finally, exhaustion.

generalization Process by which a behavior occurs in a setting in which it had not previously been reinforced.

generalized anxiety *See* free-floating anxiety.

generalized anxiety disorder An anxiety disorder characterized by chronic generalized anxiety consisting of feelings of tension, tremor, apprehension, and hyperarousal not attached to any particular idea, object, or event. *See* free-floating anxiety.

generalized tonic–clonic seizure Generalized onset of tonic–clonic movements of the limbs, tongue biting, and incontinence followed by slow, gradual recovery of consciousness and cognition. Also called grand mal seizure.

general paralysis, general paresis Mental disorder caused by chronic (tertiary) neurosyphilis.

general systems theory Theoretical framework asserting that the universe is composed of interacting components that are interrelated; in psychiatry, it emphasizes an integrated, holistic approach to understanding behavior.

Telegram: @medical_k

www.konkur.in

genetic counseling Presentation and discussion, generally with a prospective parental couple, of factors involved in the inheritance of pathologic conditions as they relate to the couple's generic endowment.

genetic endowment Characteristics that are inherited, usually regarding potential capacities of intelligence, temperament, and general adaptability.

genetic marker Detectable sign of the presence of or vulnerability to inherited disease, such as a measurable biochemical abnormality or an identifiable defect in a particular gene.

genetic material In psychiatry and psychoanalysis, a term used to reflect the data from a patient's personal past history that are useful in developing an understanding of the psychodynamics of their present adaptation.

genital phase Final stage of psychosexual development, occurring during puberty, in which sexual gratification is achieved from genital-to-genital contact and the capacity exists for a mature, affectionate relationship with someone of the opposite sex.

genotype Genetic endowment of a person, consisting of a set of genes received from each parent at the time of conception. *Compare* phenotype.

geriatric psychiatry Branch of psychiatry concerned with the mental disorders that accompany old age. Also called geropsychiatry.

geriatrics Branch of medicine concerned with the aged and the problems of aging. *See also* gerontology.

genito–pelvic pain/penetration disorder Diagnostic category in DSM-5 referring to one or more of the following: genito–pelvic pain; difficulty having intercourse; fear of pain or penetration; and tension of the pelvic floor muscles; previously divided into the distinct categories of dyspareunia and vaginismus.

gerontology Scientific study of aging.

gerontophilia Sexual attraction for the old and the aged by a young person.

gerontophobia Fear of the older adults or of the aging process.

geropsychiatry GERIATRIC PSYCHIATRY.

Telegram: @medical_k

www.konkur.in

Gerstmann–Straussler–Scheinker disease DEVELOPMENTAL ARITHMETIC DISORDER.

Gesell Developmental Schedules Developmental landmarks in infants and children that cover ages 8 weeks to 3.5 years. Data are obtained by direct observation of the child's responses to standard toys and other controlled stimulus objects and are supplemented by developmental information provided by the mother or primary caretaker; the schedules yield scores indicating the child's level of development in four separate areas: motor, adaptive, language, and personal and social.

gestalt psychology School of psychology primarily concerned with perceptual processes; a major tenet is that the whole is greater than the sum of its parts. Its development is associated particularly with Max Wertheimer, Wolfgang Koehler, and Kurt Koffka.

gestalt therapy Psychotherapy developed by Frederick S. Perls that emphasizes the treatment of the person as a whole: one's biologic component parts and their organic functioning, one's perceptual configuration, and one's interrelationships with the outside world. It can be used in either an individual or a group therapy setting; focuses on the sensory awareness of the person's here-and-now experiences, rather than on past recollections or future expectations; and uses role playing and other techniques to promote the patient's growth process and development to full potential.

Gilles de la Tourette syndrome *See* Tourette disorder.

global aphasia Combination of grossly nonfluent aphasia and severe fluent aphasia.

Global Assessment of Functioning Scale (GAF Scale) Scale used in DSM to describe the highest social, occupational, or educational level of functioning of a person in the 12 months preceding the current evaluation.

global developmental delay Preferred term for a condition of intellectual and adaptive impairment in children that fail to meet expected developmental milestones in multiple areas of

Telegram: @medical_k

www.konkur.in

intellectual functioning before 5 years of age. *See also* intellectual disability.

globus hystericus Hysterical symptom in which a person is disturbed by the sensation of a lump in the throat.

glossolalia Unintelligible jargon that has meaning to the speaker but not to the listener. Occurs in schizophrenia.

go-around Technique used in group therapy in which the therapist requires each member of the group to respond to another member, a theme, or an association to encourage the participation of all members in the group.

gonadal dysgenesis TURNER SYNDROME.

grandiose delusion DELUSION OF GRANDEUR. *See* delusion.

grandiosity Exaggerated feeling of one's importance, power, knowledge, or identity. Occurs in delusional disorder and manic states. *See also* delusion of grandeur.

grand mal epilepsy Major form of epilepsy in which gross tonic–clonic convulsive seizures are accompanied by loss of consciousness and, often, incontinence of stool or urine; frequently preceded by an aura.

gray-out syndrome Psychosis that occurs in pilots flying at high altitudes, out of sight of the horizon.

grief Alteration in mood and affect consisting of sadness appropriate to a real loss; normally, it is self-limited. *See also* depression; mourning.

group *See* therapeutic group.

group analytic psychotherapy Term applied by S. H. Foulkes to his pioneering group therapy procedure in which interventions dealt primarily with group, rather than individual, forces and processes, and the group was used as the principal therapeutic agent.

group cohesion Mutual bonds formed between members of a group as a result of their concerted effort for a common interest and purpose; until cohesiveness is achieved, the group cannot concentrate its full energy on a common task.

group dynamics Phenomena that occur in groups from their inception to their termination. Interactions and interrelations

Telegram: @medical_k

www.konkur.in

among members and between the members and the therapist create tension, which maintains a constantly changing group equilibrium; interactions and the tension created are highly influenced by individual members' psychological makeup, unconscious instinctual drives, motives, wishes, and fantasies. Understanding and effectively using group dynamics are essential in group treatment. Also called group process.

group mind Autonomous and unified mental life in an assemblage of people bound together by mutual interests; a concept used by group therapists who focus on the group as a unit rather than on the individual members.

group practice Delivery of medical services by three or more physicians formally organized to provide care, consultation, diagnosis, and treatment; they share the use of equipment and personnel, and income from the medical practice is distributed among the members of the group.

group pressure Demand by group members that individual members submit and conform to group standards, values, and behavior.

group process GROUP DYNAMICS.

group psychotherapy Application of psychotherapeutic techniques to a group of patients, using interpatient interactions to effect changes in the maladaptive behavior of the individual members.

group relations theory *See* Allport's group relations theory.

GSR Galvanic skin response.

guardianship Person appointed by the courts for the care and management of a person or the property of another, as of a minor or a person incapable of managing their affairs.

guilt Emotional state associated with self-reproach and the need for punishment. In psychoanalysis, refers to a neurotic feeling of culpability that stems from a conflict between the ego and the superego that begins developmentally with parental disapproval and becomes internalized as conscience in the course of superego formation. Guilt has normal psychological and social functions, but special intensity or absence of guilt characterizes

Telegram: @medical_k

www.konkur.in

many mental disorders, such as depression and antisocial personality disorder, respectively. Some psychiatrists distinguish shame as a less internalized form of guilt that relates more to others than to the self. *See also* shame.

gustatory hallucination Hallucination primarily involving taste.

gynecomastia Female-like development of the male breasts; may occur as an adverse effect of antipsychotic and antidepressant drugs due to increased prolactin levels or anabolic–androgenic steroid abuse.

gynephobia Abnormal fear of women.

gyrectomy Psychosurgery involving excision of a cerebral gyrus.

H

habeas corpus Legal term for the right to petition a court to decide whether confinement has been undertaken with due process of law.

habit Behavior pattern acquired by frequent repetition that leads to regularity or increased facility of performance.

habituation 1. Simple form of learning in which the response to a repeated stimulus lessens over time. **2.** Psychological dependence on the continued use of a drug or chemical substance to maintain a sense of well-being, which can result in addiction.

halfway house Facility for mental patients who no longer need the full facilities of a hospital but are not yet ready to return to their communities.

hallucination False sensory perception occurring in the absence of any relevant external stimulation of the sensory modality involved. For types of hallucination, see the specific term.

hallucinogenic drug, hallucinogen Chemical agent that produces hallucinations, such as LSD and mescaline. *See also* euphorohallucinogen; psychotomimetic drug.

hallucinosis State in which a person experiences hallucinations without any impairment of consciousness.

haloperidol Butyrophenone antipsychotic drug (trade name, Haldol).

Telegram: @medical_k

www.konkur.in

Halstead–Reitan Scale Battery of neuropsychological tests used to determine the location and effects of specific brain lesions. A great variety of functions are tested: concept function, abstraction, and visual acuity; dexterity; spatial memory; auditory perception, attention, and concentration; finger-oscillation; speech-sounds perceptions; visual perception; time sense; and sensory stimulation, stereognosis, and tactile perception.

Hamilton Depression Scale Scale of depression based upon a clinical interview with the patient in which the examiner asks about guilt, suicide, sleep habits, weight change, and other symptoms of depression.

haphephobia Abnormal fear of being touched.

haplology Rapid speech in which syllables are omitted; seen in certain manias and in schizophrenic conditions.

haptic hallucination Hallucination of touch.

harm avoidance A term used to describe a character trait in which the person avoids novel situations and taking risks; may be an inborn and genetically determined.

hashish Dried resinous tops of the marijuana plant (*Cannabis sativa*): the active ingredient is tetrahydrocannabinol, which is a potent psychedelic drug.

Health and Human Services Federal organization composed of the following: Office of Human Development Services, Public Health Service (includes Centers for Disease Control; Food and Drug Administration; Health Resources and Services Administration; National Institutes of Health; Alcohol, Drug Abuse, and Mental Health Administration; Agency for Toxic Substances and Disease Registry; and Indian Health Service), Social Security Administration, Health Care Financing Administration, and Family Support Administration. Formerly called Department of Health, Education, and Welfare (HEW).

health insurance Insurance that reimburses one for the costs of medical care or lost income arising from medical disability; may include coverage for the care of mental conditions.

health maintenance organization (HMO) Form of group practice by physicians, often including psychiatrists, and allied health

Telegram: @medical_k

www.konkur.in

professionals to provide comprehensive health services to subscribers who pay a fixed premium.

Health Systems Agency (HSA) Nonprofit, federally mandated, statewide organizations that promote or limit the development of health services and faculties depending on the needs of the particular state or locale. HSAs develop long- and short-term goals and plans, approve health care proposals requesting federal funding, review existing facilities and services, and suggest future consideration and renovation projects based on their findings.

healthy identification Modeling of oneself, consciously or unconsciously, on another person who has a sound psychic makeup; such identification has constructive results. *See also* imitation.

hearsay Out-of-court statement offered to prove the truth of the matter asserted; usually inadmissible as testimony.

hebephrenia Complex of symptoms, considered a form of schizophrenia, characterized by wild or silly behavior or mannerisms, inappropriate affect, frequent hypochondriacal complaints, and delusions and hallucinations that are transient and unsystematized. *See also* schizophrenia.

hedonism Pleasure-seeking behavior. *Compare* anhedonia.

helplessness 1. Learned: State of apathy that occurs as a type of experimental neurosis in animals who cannot escape an aversive stimulus; proposed as the animal model of human depression in which a patient feels helpless to control events. **2.** Psychic: State that occasions the first expressions of anxiety in humans, for example, the experience of birth.

hematophobia Abnormal fear of the sight of blood.

herd instinct Desire to belong to a group and to participate in social activities; used by Wilfred Trotter to indicate the presence of a hypothetical social instinct in humans. In psychoanalysis, herd instinct is viewed as a social phenomenon, rather than as an instinct.

hermaphrodite Person who has both female and male gonadal tissue, usually with one sex dominating.

Telegram: @medical_k

www.konkur.in

heroin Diacetylmorphine; an illicit, addictive alkaloid opioid that requires subsequent larger and larger amounts to achieve the same narcotic and analgesic effects. Injected intravenously, it produces a more rapid onset of euphoria than does morphine.

heterogeneity Dissimilarity in the genotypal structure of individuals originating through sexual reproduction.

heterosexuality Sexual attraction or contact between opposite-sex persons. The capacity for heterosexual arousal is probably innate, biologically programmed, and triggered in very early life, perhaps in part by olfactory modalities as seen in lower animals. *Compare* bisexuality; homosexuality.

heterozygous Possessing different allelic forms of a gene at a given locus in homologous chromosomes.

heuristic 1. Involving or serving as an aid to learning, discovery, or problem-solving by experimental and especially trial-and-error methods. **2.** Of or relating to exploratory problem-solving techniques that utilize self-educating techniques.

5-HIAA 5-Hydroxyindoleacetic acid.

histrionic personality disorder Condition in which the patient, usually an immature and dependent person, exhibits unstable, overreactive, and excitable self-dramatizing behavior that is aimed at gaining attention and is at times seductive, although the person may not be aware of that aim.

HIV Human immunodeficiency virus.

HMO Health maintenance organization.

hoarding disorder Disorder characterized by persistent difficulty parting with or discarding possessions; delusional beliefs about the accumulated items may be present. Part of obsessive-compulsive disorder in DSM-5.

holism In psychiatry, the study of the total person as a distinctive entity, rather than as a collection of various characteristics.

holophrastic Using a single word to express a combination of ideas; schizophrenic persons may use holophrastic language.

homeless Persons who have no permanent place of residence, often sleeping in the street, many of whom require psychiatric treatment or hospitalization.

Telegram: @medical_k

www.konkur.in

homeostasis Tendency to maintain a constancy and stability of bodily processes to ensure optimal functioning; the state of bodily equilibrium and the processes whereby such equilibrium is maintained.

homophobia Fear of homosexual persons.

homosexuality Sexual attraction or contact between same-sex persons. Some authors distinguish two types: overt and latent. *Compare* bisexuality; heterosexuality. When referring to people, homosexual is considered derogatory and the preferred terms are gay and lesbian.

homosexual panic Sudden, acute onset of severe anxiety precipitated by the unconscious fear or conflict that one may be a homosexual or act out homosexual impulses.

homovanillic acid (HVA) Phenol found in human urine; as the major metabolite of dopamine, it is most often measured in psychiatric research.

Horney, Karen (1885–1952) Psychiatrist and psychoanalyst whose theories of the genesis of neurosis emphasized environmental and cultural factors and thus departed from the biologic-instinctual framework of orthodox freudian thought.

hostile transference *See* transference.

hostility Conflict, opposition, or resistance in thought or principle.

hotline Telephone assistance service for crisis intervention.

HSA Health Systems Agency.

5-HT 5-Hydroxytryptamine.

human immunodeficiency virus (HIV) An infection caused by a retrovirus that incorporates itself into deoxyribonucleic acid (DNA). Symptoms include fever, myalgia, headache, fatigue, gastrointestinal symptoms, and rash. Can cause acquired immunodeficiency syndrome (AIDS).

humanistic theory Group of diverse theories that share a holistic conceptualization that emphasizes the uniqueness, value, dignity, and worth of each human being as an individual. Human behavior is considered understandable only in terms of the meaning of experiences for the individual person; it represents a complex

Telegram: @medical_k

www.konkur.in

interplay of numerous physical, psychological, and sociocultural factors.

humiliation Sense of disgrace, dishonor, and shame; often experienced by depressed patients.

humor Defense mechanism that allows the overt expression of feelings and thoughts without personal discomfort or immobilization and does not produce an unpleasant effect on others; allows the individual to tolerate and yet focus on what is too terrible to be borne. Differs from wit, a form of displacement that involves distraction from the affective issue.

Huntington disease (chorea) Hereditary and progressive central nervous system disease characterized by jerking motions and progressive mental deterioration: inherited as an autosomal dominant, with onset in adult life.

HVA Homovanillic acid.

hydrocephalus Excessive accumulation of cerebrospinal fluid which dilates the cerebral ventricles.

hydrophobia In psychiatry and psychology, an abnormal fear of water.

hydrotherapy Use of water by external application in the treatment of disease.

5-hydroxyindoleacetic acid (5-HIAA) Metabolite of serotonin, the concentration of which can be measured in cerebrospinal fluid and serum: determination of 5-HIAA concentrations is used in psychiatric research and may help guide clinical practice.

5-hydroxytryptamine (5-HT) SEROTONIN.

hyperactivity Increased muscular activity. The term is commonly used to describe a disturbance found in children that is manifested by constant restlessness, overactivity, distractibility, and difficulties in learning. Also called hyperkinesis. *See also* attention-deficit hyperactivity disorder; minimal brain dysfunction.

hyperalgesia Excessive sensitivity to pain. Seen in somatoform disorder.

hyperarousal A state of increased psychological and physiologic tension marked by such effects as reduced pain tolerance, anxiety,

Telegram: @medical_k

www.konkur.in

exaggeration of startle responses, insomnia, fatigue, and accentuation of personality traits.

hyperesthesia Increased sensitivity to tactile stimulation.

hyperkinesis HYPERACTIVITY.

hyperkinetic syndrome Disorder characterized by excessive muscular activity (hyperactivity) such as restlessness, aggressiveness, and destructive activity. *See also* attention-deficit hyperactivity disorder; minimal brain dysfunction.

hypermnesia Exaggerated degree of retention and recall. It can be elicited by hypnosis and may be seen in certain prodigies; also may be a feature of obsessive-compulsive disorder (OCD), some cases of schizophrenia, and manic episodes of bipolar I disorder.

hyperorexia Extreme appetite. *See also* bulimia nervosa.

hyperphagia Increase in appetite and intake of food.

hyperpragia Excessive thinking and mental activity, generally associated with the manic phase of bipolar I disorder.

hypersexuality Term used to describe excessive or compulsive interest in sex that may result in sex addiction.

hypersomnia Disorder characterized by excessive time spent asleep which may be nonorganic, organic, narcoleptic, idiopathic, part of Klein–Levin syndrome, or primary in nature. Also called hypersomnolence disorder.

hypersomnolence disorder *See* hypersomnia.

hypertensive crisis HYPERTENSIVE ENCEPHALOPATHY.

hypertensive encephalopathy Acute syndrome in which severe hypertension is associated with headache, nausea, vomiting, visual disturbances, convulsions, and alterations in consciousness characterized by confusion, somnolence, stupor, and coma. Prompt lowering of the blood pressure by pharmacologic means may reverse the picture in 24 to 48 hours; if the blood pressure is not controlled, intracerebral hemorrhage and a fatal outcome may result. Usually, the patient has entered the malignant phase of essential or secondary hypertension, with marked blood pressure elevation (generally in the range of 250/150 mm Hg) and evidence of cardiac decompensation, declining renal function, and

Telegram: @medical_k

www.konkur.in

advanced hypertensive retinopathy; also seen as a side effect of monoamine oxidase inhibitors when tyramine-containing foods are consumed. Also called hypertensive crisis.

hyperthyroidism Excessive activity of the thyroid gland; may be associated with dementia, anxiety disorders, and insomnia. *Compare* hypothyroidism.

hyperventilation Excessive breathing, generally associated with anxiety, which can cause a reduction in blood carbon dioxide that produces symptoms of lightheadedness, palpitations, numbness and tingling periorally and in the extremities, and occasionally syncope.

hypervigilance Excessive attention to and focus on all internal and external stimuli; usually seen in delusional or paranoid states.

hypesthesia Diminished sensitivity to tactile stimulation.

hypnagogic hallucination Hallucination occurring while falling asleep, not ordinarily considered pathologic.

hypnoanalysis Use of hypnosis in psychoanalysis to gain access to unconscious processes that the patient cannot reveal by means of ordinary therapeutic maneuvers.

hypnodrama Psychodrama under hypnotic trance; the patient is put into a hypnotic trance and encouraged to act out various past experiences.

hypnoid state Freud's term describing an alteration of consciousness that occurs characteristically in hysteria during periods of emotional stress: characterized by heightened suggestibility and provides a basis for hysterical somatic symptom formation.

hypnophobia Abnormal fear of sleep.

hypnopompic hallucination Hallucination occurring while awakening from sleep, ordinarily not considered pathologic.

hypnosis Artificially induced alteration of consciousness characterized by increased suggestibility and receptivity to direction.

hypnotherapy Therapy that makes use of hypnosis.

hypnotic Drug used for the express purpose of producing sleep. *Compare* sedative.

Telegram: @medical_k

www.konkur.in

hypoactive sexual desire disorder Sexual desire disorder characterized by deficiency or absence of sexual fantasies and desire for sexual activity. Also called sexual interest/arousal disorder in women.

hypoactivity Decreased motor and cognitive activity, as in psychomotor retardation; visible slowing of thought, speech, and movements. Also called hypokinesis.

hypochondria Exaggerated concern about health that is based not on real medical pathology, but on unrealistic interpretations of physical signs or sensations as abnormal.

hypochondriacal neurosis HYPOCHONDRIASIS.

hypochondriasis *See* somatic symptom disorder.

hypoglycemia Abnormally small concentration of glucose in the circulating blood; associated with anxiety and depression.

hypomania Mood abnormality with the qualitative characteristics of mania, but less intense; characterizes the hypomanic episode of bipolar II disorder when lasting 4 to 7 days.

hypothalamus Principal center in the forebrain for integration of visceral functions involving the autonomic nervous system. Functions include regulation of sexual activity, water, fat, carbohydrate metabolism, and temperature; also appears to play a role in the nervous mechanisms underlying moods and motivational states.

hypothyroidism Decreased activity of the thyroid gland; may be associated with dementia, depression, and sleep disorders. *Compare* hyperthyroidism.

hysteria A term previously used for a group of conditions involving a sudden impairment of function in response to emotional stress.

hysterical anesthesia Functional disorder characterized by the absence of tactile sensation in an area of the body; observed in certain cases of conversion disorder.

hysterical personality *See* histrionic personality disorder.

hysterics Expression of emotion often accompanied by crying, laughing, and screaming; a term generally used by laypersons rather than by psychiatrists.

Telegram: @medical_k

www.konkur.in

I

iatrogenic Denoting an unfavorable response to a mode of treatment induced by the treatment itself. *Compare* idiopathic.

ICD *International Classification of Diseases.*

ice Pure form of methamphetamine that can be either inhaled or injected intravenously by abusers; its psychological effects last for hours and are particularly potent. Unlike the crack cocaine, which has to be imported, ice is a synthetic drug that can be manufactured in domestic illicit laboratories.

ICT Insulin coma therapy.

Id One of the three components of the psychic apparatus in the Freudian structural framework, the others being the ego and superego. It operates unconsciously; harbors the innate, biologic, instinctual drives; is the source of psychic energy (libido); follows the pleasure principle; seeks immediate reduction of drive tension without regard for external reality; and is under the influence of the primary-process mental activity that characterizes the unconscious.

idealization Mental mechanism whereby a person consciously or unconsciously overestimates an admired attribute or aspect of another person.

idea of reference Misinterpretation of incidents and events in the outside world as having a direct personal reference to oneself; occasionally observed in normal persons, but frequently seen in paranoid patients. If present with sufficient frequency or intensity or if organized and systematized, they constitute delusions of reference.

ideas of unreality Thought that events are artificial, illusory, unpredictable, or do not exist.

ideational shield Intellectual, rational defense against the anxiety that persons would feel if they became vulnerable to the criticisms and rejection of others; as a result of their fear of being rejected, they may feel threatened if they criticize another person, an act that is unacceptable to them. In both group and individual therapy,

Telegram: @medical_k

www.konkur.in

conditions are set up that allow the participants to lower the ideational shield.

idée fixe Fixed idea that is recurrent and most often associated with obsessional states.

identical twins MONOZYGOTIC TWINS.

identification Unconscious defense mechanism by which a person patterns themself after another person; in the process, the self is more or less permanently altered. *See also* healthy identification; imitation.

identification with the aggressor Unconscious process by which a person incorporates within themself the mental image of a person who represents a source of frustration from the outside world; a primitive defense that operates in the interest and service of the developing ego. A classic example of this defense occurs toward the end of the oedipal stage, when a boy, whose main source of love and gratification is his mother, identifies with his father who represents the source of frustration, being the powerful rival for the mother; the child cannot master or run away from his father, so he is obliged to identify with him.

identity One's global role in life and the perception of the sense of self; problems with identity are common during adolescence, in schizophrenia, and in the borderline and schizotypal personalities.

identity crisis Social role conflict as perceived by a person; loss of the sense of personal sameness and historical continuity, and/or inability to accept or adopt the role the person believes is expected by society. Identity crises are frequent in adolescence.

identity disorder A disorder characterized by a chaotic sense of self; a loss of the sense of personal sameness, usually involving a social role conflict as perceived by the individual. It is common in adolescence, when adolescents feel unwilling or unable to accept or adopt the roles they believe are expected of them by society; often manifested by isolation, withdrawal, rebelliousness, negativity, and extremism. Not a DSM-5 diagnosis.

idiopathic Without known or identifiable cause. *Compare* iatrogenic.

Telegram: @medical_k

www.konkur.in

idiot Obsolete and pejorative term for a classification of mental retardation in which individuals have a mental age of less than 3 years.

idiotropic Egocentric or introspective.

idiot-savant Mentally retarded person who is able to perform unusual mental feats in sharply circumscribed intellectual areas, such as complicated calculations or puzzle solving.

I-It Philosopher Martin Buber's description of damaging interpersonal relationships. If a person treats themself or another person exclusively as an object, they prevent mutuality, trust, and growth. When pervasive in a group, I-It relationships prevent human warmth, destroy cohesiveness, and retard group process. *Compare* I-Thou.

illness anxiety disorder Preoccupation with being sick or developing a disease with few or no somatic symptoms and an absence of related pathologies found on medical examination. Differentiated from somatic symptom disorder (hypochondriasis) by the absence of somatic symptoms or complaints; patients with illness anxiety disorder are primarily concerned with "the idea" of being or becoming sick; a DSM-5 diagnosis. *Compare* somatic symptom disorder.

illogicality Pattern of speech or thinking in which conclusions that are reached do not follow logically; may take the form of unwarranted or faulty inferences.

illogic thinking Thinking containing erroneous conclusions or internal contradictions; psychopathologic only when it is marked and not caused by cultural values or intellectual deficit.

illuminism State of hallucinations in which a patient converses with imaginary supernatural creatures.

illusion Perceptual misinterpretation of a real external stimulus. *Compare* hallucination.

imago Jungian term referring to an idealized unconscious mental image of a key person in someone's early life.

imbecile Obsolete and pejorative term for a classification of mental retardation in which individuals have a mental age of 3 to 7 years.

Telegram: @medical_k

www.konkur.in

imitation Duplication or mimicking of behaviors or portions of behaviors observed in a model. *See also* identification.

immediate memory Reproduction, recognition, or recall of perceived material within seconds after presentation. *Compare* long-term memory; short-term memory.

impaired insight Diminished ability to understand the objective reality of a situation.

impaired judgment Diminished ability to understand the objective reality of a situation. *See also* judgment.

implosion Behavior therapy technique in which anxiety-arousing stimuli are vividly presented in imagination; the patient repeatedly experiences intense anxiety in the absence of objective danger until the anxiety response is extinguished.

impotence A term used to refer to the inability to obtain an erection. In DSM, it is diagnosed as erectile disorder.

imprinting Particular kind of learning that occurs during an early critical developmental stage in animals, characterized by rapid acquisition and great resistance to extinction. It seems to represent a biologically predetermined proclivity to learn certain persistent species-specific behavior patterns, give exposure to the proper stimulus during the critical stage, but its precise role in human behavioral development has not been established.

improvisation In psychodrama, the acting out of situations without prior preparation.

impulse Psychic striving or urge to perform an action. *See also* drive; instinct.

impulse control Ability to resist an impulse, drive, or temptation to perform some action.

impulse-control disorders Mental disorders in which there is weak impulse control with impulsive behavior that is usually irresistible, pleasurable, and aimed at obtaining immediate gratification, without regard for the consequences of the behavior, for example, pathologic gambling, kleptomania, pyromania, intermittent explosive disorder, trichotillomania.

impulsion Blind following of internal drives without regard for social acceptance or pressure from the superego, normally seen in

Telegram: @medical_k

www.konkur.in

young children. In adults, it is common in those with weak defensive organizations; in such cases it tends to be a symbolic phenomenon.

inappropriate affect Emotional tone out of harmony with the idea, thought, or speech accompanying it. Seen in schizophrenia.

incest Sexual activity between close blood relatives. Common patterns are father–daughter, mother–son, and between siblings; may also be same sex.

incidence Research term for the number of cases of a disease whose onset occurs during a specific period of time. *See also* prevalence.

incidence rate Rate at which new cases of a disease or a condition are occurring. The incidence rate per 1,000 persons in the population is the number of new cases that occur within a defined unit of time, divided by the persons exposed or at risk during the same time unit, multiplied by 1,000.

incoherence Communication that is disconnected, disorganized, or incomprehensible. *See also* word salad.

incompetence Legal term indicating that thought processes are inadequate for sound judgment and may lead to maladaptive or abnormal behavior; legally, incompetent persons cannot be held responsible for their actions.

incorporation Primitive unconscious defense mechanism in which the psychic representation of another person or aspects of another person are assimilated into oneself through a figurative process of symbolic oral ingestion; represents a special form of introjection and is the earliest mechanism of identification.

increased libido Increase in sexual interest and drive. Often associated with mania.

independent variable In research methodology, those qualities that the experimenter systematically varies, for example, time, dosage.

individual psychology System of psychiatric theory developed by Alfred Adler that stresses compensation and overcompensation for feelings of inferiority in a person's strivings to adapt to the social milieu, and emphasizes the interpersonal nature of a person's

Telegram: @medical_k

www.konkur.in

problems; applied by some practitioners to group psychotherapy and counseling.

individual therapy Traditional dyadic therapeutic technique in which a psychotherapist treats only one patient during a given therapeutic session.

individuation Jungian term denoting a process whereby the person molds and develops a healthy integrated individual personality through maximum differentiation and development of each system of the personality. *See also* actualization.

Indoklon therapy Type of biologic therapy in which a convulsive seizure is induced by the inhalation of the drug Indoklon (hexafluorodiethyl ether).

indolamine Class of biogenic amines that contain an indole ring and are derived from the essential amino acid tryptophan; includes lysergic acid diethylamide (LSD) and serotonin. Monoamine oxidase inhibitors elevate the levels of indolamines by delaying their breakdown.

induced psychotic disorder *See* shared psychotic disorder.

industrial psychiatry Branch of psychiatry concerned with workers' adjustments to their jobs and with the effects of a business organization on its members.

ineffability Ecstatic state in which a person insists that their experience is inexpressible and indescribable, that it is impossible to convey what it is like to one who never experienced it.

infancy Childhood period of helplessness and marked dependency, generally the first year of life.

infantile articulation DEVELOPMENTAL ARTICULATION DISORDER.

infantile autism A term now subsumed under autism spectrum disorder that refers to a syndrome beginning in infancy and characterized by withdrawal and self-absorption, failure to develop attachment to a parental figure, ineffective communication and mutism, preoccupation with inanimate objects, and an obsessive demand for sameness in the environment. Also called Kanner syndrome; autistic spectrum disorder. *See also* autistic thinking.

Telegram: @medical_k

www.konkur.in

infantile dynamics Psychodynamic integrations, such as the Oedipus complex, that are organized during childhood and continue to exert an unconscious influence on adult personality.

infantile perseveration DEVELOPMENTAL ARTICULATION DISORDER.

infantile sexuality Freudian concept regarding the erotic life of infants and children, that, from birth, infants are capable of erotic activities; encompasses the overlapping phases of psychosexual development during the first 5 years of life and includes the oral phase (birth to 18 months), the anal phase (ages 1 to 3), and the phallic phase (ages 2 to 6).

infant psychiatry That aspect of child psychiatry concerned with the diagnosis, treatment, and prevention of maladaptive psychological functioning in infants.

inferential statistics Methods used for drawing general conclusions about probabilities on the basis of a sample. *See also* statistical inference.

inferiority complex Concept, originated by Alfred Adler, that everyone is born with a feeling of inferiority or inadequacy secondary to real or fantasied organic or psychological deficits; how the inferiority or feeling of inferiority is handled determines a person's behavior in life. *See also* masculine protest.

informal admission As a general hospital model, a patient admitted to a psychiatric unit is free to enter and to leave, even against medical advice.

information theory System dealing with the transmission, reception, and distortion of communicated messages.

informed consent Consent given by a patient to a physician to perform a procedure legally requires that the patient be informed of the nature of the proposed procedure, its risks, its proposed benefits, and the available alternatives; the major problem in giving informed consent, legally and psychologically, is the extent or depth of disclosure.

infradian rhythm *See* biologic rhythm.

infusion Introduction of fluid other than blood, for example, medicines, into a vein.

Telegram: @medical_k

www.konkur.in

inhalant Substance taken in by breathing. Production of psychoactive effects by the ingestion of such volatile substances as gasoline, airplane glue, aerosols (especially spray paints), or rubber cement, warrants the DSM diagnosis of inhalant dependence or inhalant abuse.

inhibited female orgasm Recurrent and persistent inhibition (absence) of the female orgasm, referring to the inability of a female to achieve orgasm by masturbation or coitus. Also called anorgasmia.

inhibited male orgasm Difficulty or inability of a male in achieving ejaculation during coitus. Also called ejaculatory incompetence; retarded ejaculation. *See also* primary retarded ejaculation; secondary retarded ejaculation.

inhibited sexual excitement Former term for female sexual arousal disorder.

inhibition Limitation or renunciation of ego functions occurring consciously, alone or in combinations, to evade anxiety arising out of conflict with instinctual impulses, the superego, or environmental forces or figures.

initial insomnia Falling asleep with difficulty; usually seen in anxiety disorder. *Compare* middle insomnia; terminal insomnia.

insane Of or pertaining to one who is of unsound mind. A legal rather than a psychiatric term.

insanity Legal concept denoting a mental disturbance, due to which a person lacks criminal responsibility for an alleged crime and hence cannot be convicted of the crime. *See also* American Law Institute formulation of insanity; Durham rule; M'Naghten rule.

insanity defense Criminal law defense plea that a person lacks criminal responsibility by reason of insanity.

insecurity Feelings of helplessness, unprotectedness, and inadequacy in the face of manifold anxieties arising from uncertainty regarding one's goals, ideals, abilities, and relations to others.

insight Conscious recognition of one's own condition. In psychiatry, it more specifically refers to the conscious awareness and understanding of one's own psychodynamics and symptoms of

Telegram: @medical_k

www.konkur.in

maladaptive behavior; highly important in effecting changes in the personality and behavior of a person.

insight-oriented psychotherapy Psychotherapy based on the principles of psychoanalysis in which persons develop a conscious awareness and understanding of their own psychodynamics and symptoms of maladaptive behavior. There is greater emphasis on day-to-day reality issues and a lesser emphasis on the development of transference issues than in psychoanalysis.

insight therapy *See* insight-oriented psychotherapy.

insomnia disorder Difficulty in falling asleep or difficulty in staying asleep. It can be related to another mental disorder (nonorganic), can be related to a known organic factor (such as a physical disorder or a medication), or can be primary (not related to a known organic factor or to another mental disorder). *See also* initial insomnia; middle insomnia; terminal insomnia.

instinct Basic inborn urge or drive. Freud postulated the existence of two opposing primal instincts: a life instinct (eros) and a death instinct (thanatos). An extensive array of human instincts has been proposed, including possessive instinct, mastery instinct, and herd or social instinct. Because of its implication of a fixed, essentially unalterable, largely hereditary response or psychic tendency that does not involve learning or reason, the term has become ambiguous and controversial when applied to human behavior. Many modern psychoanalysts prefer the term “drive” for what Freud termed “instinct.” *See also* drive.

institutionalization Process of placing a patient in a facility for extended care, for example, a mental hospital or nursing home.

instrumental conditioning OPERANT CONDITIONING. *See* conditioning.

insulin coma therapy (ICT) Type of biologic therapy in which large amounts of insulin are given to a psychotic patient, usually a schizophrenic, producing profound hypoglycemia and resulting in a coma; introduced by Manfred Sakel in 1933, it declined in use drastically after the introduction of antipsychotic drugs. An occasionally used early stage of this treatment is called subcoma therapy.

Telegram: @medical_k

www.konkur.in

intake Initial interview between a patient and a member of a psychiatric team, a term usually used in connection with admission to a mental health facility.

integration Constructive organizing, absorbing, and incorporating into the personality of data and experience; also refers to an amalgamation of separate parts into a functioning integral whole.

intellectual disability (ID) or intellectual developmental disorder Below average general intellectual functioning with concurrent impairment in adaptive behaviors, such as communication, self-care, and interpersonal skills, which manifests before adulthood. In DSM-5, the degree of ID is classified as mild, moderate, severe, or profound based on overall level of functioning. Previously called mental retardation.

intellectual insight Knowledge of the reality of a situation without the ability to successfully use that knowledge to effect an adaptive change in behavior. *Compare* true insight.

intellectualization Unconscious defense mechanism in which reasoning or logic is used in an attempt to avoid confrontation with an objectionable impulse and thus defend against anxiety. Also called brooding compulsion; thinking compulsion.

intellectual subaverage functioning IQ of more than two standard deviations below the test mean obtained on an intelligence test.

intelligence Capacity for learning and ability to recall, integrate constructively, and apply what one has learned; the capacity to understand and to think rationally.

intelligence quotient (IQ) Numerical measure of mental capability determined by dividing a mental age (MA) score achieved on a specific test, such as the Stanford–Binet Test, by the patient's chronologic age (CA) and multiplying by 100.

intermission In psychiatry, the interval between attacks of a particular syndrome; when it is not certain that the symptoms will return, the interval is called a remission.

intermittent explosive disorder Condition in which a person has discrete episodes of losing control of aggressive impulses resulting in serious assault or destruction of property; often caused by a disorder of brain physiology, particularly in the limbic system.

Telegram: @medical_k

www.konkur.in

intermittent reinforcement Any schedule of reinforcement in which the response is not always reinforced.

***International Classification of Diseases* (ICD)** World Health Organization's official list of disease categories subscribed to by all WHO member nations. ICD-CM is ICD's clinical modification, first published in 1919.

internship First year of clinical training following medical school, now called postgraduate year I (PGY-I), which progresses onto residency training in a specialty area.

interobserver reliability Degree of concurrence or disagreement among observers of a single event.

interpersonal conflict EXTRAPSYCHIC CONFLICT.

interpersonal psychiatry Dynamic-cultural system of psychiatry based on Harry Stack Sullivan's interpersonal theory, which proposes that each person must be viewed as an entity interacting with the sociocultural and interpersonal environment; emphasis is on interactive experiences.

interpersonal psychotherapy A type of brief psychotherapy used primarily for the treatment of depression. In a course of 10 to 12 sessions the therapist and patient focus of current problems with person in the environment which increases the patient's perception of self-defeating behaviors that contribute to low self-esteem and depression.

interpersonal skill Effectiveness of adaptive behavior in relation to other persons; ability to express feelings appropriately, to be socially responsible and responsive, and to work in harmony with others.

interpretation The formulation or description by the therapist to the patient of the therapist's understanding of the symbolic significance or meaning of any aspect of the patient's intrapsychic processes, behavior, or verbal productions; an attempt is made to construct into a more meaningful form the patient's resistances, defenses, transferences, and other symbolic activities, for example, dreams, fantasies.

Telegram: @medical_k

www.konkur.in

Interpretation of Dreams The Sigmund Freud's major presentation (1899) not only of his theories about the meaning of dreams, a subject hitherto regarded as outside scientific interest, but also of his concept of a mental apparatus topographically divided into unconscious, preconscious, and conscious areas.

interview Person-to-person interaction in which information about a subject is collected. *See also* structured interview; unstructured interview.

intoxication Organic mental disorder due to the recent ingestion or presence in the body of an exogenous substance producing maladaptive behavior by virtue of its effects on the central nervous system. The most common psychiatric changes involve disturbances of perception, wakefulness, attention, thinking, judgment, emotional control, and psychomotor behavior; the specific clinical picture depends on the nature of the substance ingested. For types of intoxication, see the specific term.

intrapersonal conflict INTRAPSYCHIC CONFLICT.

intrapsychic Referring to what originates, takes place, or is situated within the psyche or mind.

intrapsychic ataxia *See* ataxia.

intrapsychic conflict State of tension arising from the clash of two or more incompatible or opposing forces; for example, wishes, needs, motives, thoughts operating within oneself. Also called intrapersonal conflict. *Compare* extrapsychic conflict.

intravenous Denoting introduction of a substance into a vein or veins. *See also* infusion.

introjection Unconscious, symbolic internalization of a psychic representation of a hated or loved external object with the goal of establishing closeness to and constant presence of the object; considered an immature defense mechanism. In the case of a loved object, anxiety consequent to separation or tension arising out of ambivalence toward the object is diminished; in the case of a feared or hated object, internalization of its malicious or aggressive characteristics serves to avoid anxiety by symbolically

Telegram: @medical_k

www.konkur.in

putting those characteristics under one's own control. *See also* incorporation.

intropunitive Turning anger inward toward oneself; commonly observed in depressed patients.

introspection Contemplating one's own mental processes so as to achieve insight.

introversion State in which a person's energies are directed inward toward the self, with little or no interest in the external world. *Compare* extroversion.

introverted personality disorder SCHIZOID PERSONALITY DISORDER.

inversion Sigmund Freud's term for homosexuality, in which he distinguished three types: absolute, amphigenous, and occasional.

involuntary admission Hospitalization of a person against their will. Following an application by a friend or relative for the admittance of a person who does not recognize the need for hospital care, certification by two physicians is required, which allows the patient to be hospitalized for 60 days. Patients have access to legal counsel and, if brought to court, a judge can order the patient's release. After 60 days, the case must be reviewed by a board (of psychiatrists, physicians, lawyers, and citizens not affiliated with the hospital). *See also* parens patriae.

involuntary discharge Termination of hospitalization against a patient's will.

involuntary treatment Care of a person, who has a mental disorder that constitutes a danger to self or others, against that person's will.

involutional melancholia Depression occurring in late middle-age in persons who generally have no history of previous mental illness. Characteristic manifestations include delusions of sin, guilt, or poverty; an obsession with death; preoccupation with somatic (particularly gastrointestinal) function; despair, dejection, agitation, anxiety, and insomnia; and, in some cases, paranoid ideation. The term is not used in DSM-5, but is replaced by the diagnosis of major depressive episode, melancholic type. Also called involutional psychosis.

Telegram: @medical_k

www.konkur.in

involutional psychosis *See* involutional melancholia.

IQ Intelligence quotient.

irregular sleep phase circadian rhythm disorder A circadian rhythm sleep–wake disorder characterized by a fragmented, disorganized, or unpredictable sleep–wake pattern.

irrelevant answer Answer that is not responsive to the question.

irresistible impulse Concept that a person charged with a criminal offense is not responsible for their act if the act was committed under an impulse that the person was unable to resist because of mental disease. The courts have chosen to interpret this law in such a way that it has been called the "policeman-at-the-elbow" law; in other words, the court will grant the impulse to be irresistible only if it determines that the accused would have gone ahead with the act even if they had had a policeman at their elbow.

irritability Abnormal or excessive excitability, with easily triggered anger, annoyance, or impatience.

irritable mood State in which one is easily annoyed and provoked to anger. *See also* irritability.

isolated explosive disorder Disorder of impulse control in which a person has a single episode characterized by a failure to resist a violent impulse against others.

isolation In psychoanalysis, a defense mechanism involving the separation of an idea or memory from its attached feeling tone; unacceptable ideational content is thereby rendered free of its disturbing or unpleasant emotional charge. *Compare* relatedness. *See also* alienation.

isophilic Term used by Harry Stack Sullivan to mean liking or feeling affectionate toward people of the same sex, without the sexual or erotic aspects of homosexuality.

I-Thou Philosopher Martin Buber's conception that a person's identity develops from the true sharing by persons; basic trust can occur in a living partnership in which each member identifies the particular real personality of the other in their wholeness, unity, and uniqueness. In groups, I-Thou relationships promote warmth, cohesiveness, and constructive group process. *Compare* I-It.

Telegram: @medical_k

www.konkur.in

J

jacksonian epilepsy Epilepsy characterized by recurrent episodes of focal motor seizures that usually begin with a highly localized tonic contraction or clonic movement which increases in severity and spreads progressively, often involving the entire body and terminating in a characteristic generalized convulsion with loss of consciousness; implies organic cerebral disease.

jamais vu Paramnestic phenomenon characterized by a false feeling of unfamiliarity with a real situation that one has experienced.

James–Lange theory of emotion Theory that the experience of emotion is preceded by a visceral or motor response, for example, first the person runs and then feels fear.

Janet, Pierre (1859–1947) Last great representative of the French school of psychiatry, known for his concept of psychological automatism and for his interest in cases of multiple personalities; first used the term “la belle indifférence.”

jargon aphasia Aphasia in which the words produced are neologistic, that is, nonsense words created by the patient.

JCAHO Joint Commission on Accreditation of Healthcare Organizations. Formerly JCAH, Joint Commission on Accreditation of Hospitals.

JCMHC Joint Commission on Mental Health of Children.

Joint Commission on Accreditation of Healthcare Organizations (JCAHO) Group of agencies that influence the standards and performance of hospitals and health organizations; they inspect hospitals every 2 years and determine requirements for hospital accreditation (on which hospital reimbursements from Medicare and Medicaid are contingent).

Joint Commission on Mental Health of Children (JCMHC) Multidisciplinary agency authorized by U.S. Congress in 1965 to monitor the treatment of children with emotional illness.

Joint Commission on Mental Illness and Health Multidisciplinary study group established in 1955 whose “Action for Mental Health”

Telegram: @medical_k

www.konkur.in

(1961) was instrumental in the legislation and federal funding for community mental health centers; with the passage of the Community Mental Health Centers Act in 1963, deinstitutionalization became a reality.

Jones, Ernest (1879–1958) Welsh psychoanalyst, and one of Freud's early followers, who was an organizer of the American Psychoanalytic Association (1911) and of the British Psychoanalytical Society (1919) and a founder and long-time editor of the journal of the International Psychoanalytical Association; a prolific author most noted for his three-volume biography of Sigmund Freud.

judgment Mental act of comparing or evaluating choices within the framework of a given set of values for the purpose of electing a course of action. If the course of action chosen is consonant with reality or with mature adult standards of behavior, judgment is said to be intact or normal; judgment is said to be impaired if the chosen course of action is frankly maladaptive, results from impulsive decisions based on the need for immediate gratification, or is otherwise not consistent with reality as measured by mature adult standards.

Jung, Carl Gustav (1875–1961) Swiss psychiatrist and psychoanalyst, originally associated with Sigmund Freud, who later founded the school of analytic psychology.

justice In the context of mental health, a fair distribution and application of psychiatric procedures.

K

Kanner syndrome INFANTILE AUTISM.

kindling effect Electrophysiologic process in which repeated subthreshold stimulation of a neuron eventually generates an action potential; at the organ level, repeated subthreshold stimulation of an area of the brain results in the generation of a seizure.

kinesiology Study of body movement, especially in the context of its communicative function.

Telegram: @medical_k

www.konkur.in

kinesthetic hallucination Hallucination primarily involving bodily movement.

kinesthetic sense Sense by which muscular motion, tension, position, and posture are perceived. Also called proprioception.

Kirkbride, Thomas S. (1809–1883) American psychiatrist, one of the 13 original founders of the American Psychiatric Association, noted for his 1854 manual advocating reform in the design of institutions for the mentally ill.

Klein, Melanie (1882–1960) British psychoanalyst and child analyst whose theories of early development departed from orthodox freudian thought.

Kleine–Levin syndrome Condition characterized by periodic episodes of hypersomnia and bulimia.

kleptomania Pathologic compulsion to steal.

Klinefelter syndrome Chromosomal anomaly in which there is an extra X chromosome (karyotype 47-XXY). Affected persons are male in development, with small firm testes, eunuchoid habitués, variable gynecomastia and other signs of androgen deficiency, and elevated gonadotropin levels; there is an increased frequency of mental retardation (about 25%) and other forms of psychopathology, particularly antisocial behavior and delinquency. *See also* Turner syndrome.

Klüver–Bucy syndrome Behavioral syndrome, first described in monkeys after bilateral temporal lobe ablation, characterized by increased oral, sexual, and aggressive behavior; loss of visual recognition: memory defect; and hyperreactivity to visual stimuli.

Kohut, Heinz (1913–1981) Important innovator in psychoanalysis, who originated the psychoanalytic school of self-psychology, which requires that patients become aware of their excessive needs for approval and self-gratification.

koro Acute delusional syndrome, seen in Southeast Asia and southern China, in which the patient suddenly becomes acutely anxious that his penis is shrinking and may disappear into his abdomen, in which case he will die.

Korsakoff psychosis Mental disorder seen in long-term alcoholics. Its major characteristic feature is profound memory impairment,

Telegram: @medical_k

www.konkur.in

particularly for recent events, for which the individual attempts to compensate by confabulation. Called alcohol amnestic disorder in DSM. *See also* Wernicke fluent encephalopathy.

Kraepelin, Emil (1865–1926) German psychiatrist noted for his pioneering work in psychiatric nosology and classification systems, and who differentiated between manic–depressive psychoses and dementia precox (schizophrenia). One of the last representatives of the predynamic school of psychiatry, he is often considered the father of descriptive psychiatry.

Kretschmer, Ernest (1888–1964) German psychiatrist noted for his theories of the relation of physique to character and personality.

kuru A prion disease, seen in Papua, New Guinea, caused by cannibalistic funeral rituals.

L

la belle indifférence Inappropriate attitude of calm or lack of concern about one's disability; seen in patients with conversion disorder.

labile Unstable; characterized by rapidly changing emotions.

labile affect Affective expression characterized by repetitious and abrupt changes, unrelated to external stimuli.

labile mood Oscillations in mood between euphoria and depression or anxiety.

lability *See* emotional lability.

laconic speech Condition characterized by a reduction in the quantity of spontaneous speech; replies to questions are brief and unelaborated, and little or no unprompted additional information is provided. Occurs in major depression, schizophrenia, and organic mental disorders. Also called poverty of speech.

lacunar amnesia LOCALIZED AMNESIA.

lalophobia Abnormal fear of speaking. Also called glossophobia.

language disorder Persistent difficulties in the acquisition and use of language across modalities due to deficiencies in production (expressive) or comprehension (receptive-expressive) that include reduced vocabulary, difficulty with sentence formation, and

Telegram: @medical_k

www.konkur.in

impairments in discourse. Disorders lead to functional limitations in effective communication, social participation, and/or occupational performance. *See also* communication disorder.

lanugo Neonatal-like body hair; may be noted in anorexia nervosa.

lapsus linguae Slip of the tongue.

latah Culture-specific disorder found among Malaysians and characterized by either a sudden onset of unusual and inappropriate motor and verbal manifestations or by an echo reaction, in which the victim is compelled to imitate any words or actions to which they are exposed; in both forms affected persons cannot control or inhibit their behavior.

late language emergence DSM-5 disorder of early childhood characterized by delayed language onset in the absence of any developmental disabilities or delays.

late luteal phase dysphoric disorder (LLPDD) *See* premenstrual dysphoric disorder.

latency phase Period of psychosexual development after the phallic phase and succeeded by the genital phase, extending from about age 5 to the beginning of adolescence at age 12; during this phase there is an apparent cessation of sexual preoccupation and a blockade of libidinal impulses, and boys and girls are inclined to choose friends and join groups of their own sex.

latent content Hidden or unconscious meaning of symbolic representations, especially in fantasies and dreams. *See also* manifest content.

latent homosexuality Unexpressed conscious or unconscious homoerotic wishes that are held in check. Sigmund Freud's theory of bisexuality postulated the existence of a constitutionally determined, although experientially influenced, instinctual masculine–feminine duality; normally, the opposite-sex component is dormant, but a breakdown in the defenses of repression and sublimation may activate latent instincts and result in overt homoeroticism.

latent schizophrenia Condition characterized by clear schizophrenic symptoms without a history of prior overtly psychotic

Telegram: @medical_k

www.konkur.in

schizophrenic episodes. In DSM the condition is subsumed under the category of schizotypal personality disorder.

learned autonomic control Learned regulation by a person of physiologic responses that are under autonomic nervous system control. *See also* biofeedback.

learned helplessness *See* helplessness.

learning disorders Disorders manifested in school-age children and characterized by specific difficulties in learning that are unrelated to intelligence. In DSM, disorders include reading disorder, dyscalculia, and disorder of written expression. *See also* dyslexia.

learning theory Approach to the understanding of human behavior that emphasizes the way in which learning comes about. Learning itself represents a change in behavior resulting from practice; through the application of certain laws of learning, learning theory attempts to explain the basic processes that are necessary for learning to occur.

lesbianism Female homosexuality. Also called sapphism.

Lesch–Nyhan syndrome A rare, X-linked disorder caused by a deficiency of an enzyme involved in purine metabolism. Characteristics include intellectual disability, seizures, self-mutilating behaviors (e.g., head banging, finger biting), microcephaly, choreoathetosis, and spasticity.

lethologica Momentary forgetting of a name or proper noun. *See* blocking.

leukotomy LOBOTOMY.

Lewin, Kurt (1890–1947) German psychologist who emigrated to United States in 1933. Two of his chief theoretical contributions are the field approach (field theory) and group dynamics, each of which has been useful in the experimental study of human behavior in a social situation.

Lewy body disease A type of dementia clinically similar to Alzheimer disease that is also accompanied by hallucinations and parkinsonian features. Often associated with Capgras syndrome. *See also* dementia of the Alzheimer type.

Telegram: @medical_k

www.konkur.in

Liaison Committee on Medical Education (LCME) Group sponsored by the American Medical Association and the Association of American Medical Colleges that is principally involved in accrediting activities in undergraduate medical education.

liaison nursing Communication among nurses from various disciplines concerning the treatment of medical, surgical, and neuropsychiatric patients.

liaison psychiatry *See* consultation-liaison psychiatry.

libido In psychoanalysis, the psychic energy associated with the sexual drive (life instinct).

life instinct SEXUAL DRIVE.

lifetime expectancy Total probability of a person developing a disorder during a lifetime.

lifetime prevalence Measure at a point in time of the number of persons who had a given disorder at some time during their lives.

lilliputian hallucination Visual sensation that persons or objects are reduced in size, more properly regarded as an illusion. *See also* micropsia.

limbic system James Papez' proposal (1939) that a reverberating circuit or system, consisting of the hippocampus, hypothalamus, anterior thalamus, and cingulate gyrus, was the central nervous system localization for emotions; current models also include the amygdala and septal area, as well as other neuroanatomic areas. Various parts of the limbic system have been associated with emotions, sex drive, eating behavior, rage, violence, memory, and motivation.

lithium carbonate Lithium salt effective in the treatment of the manic phase of bipolar disorder and as a mood-stabilizing drug for chronic manic–depressive patients; may also be an effective antidepressant in some patients.

Little Albert Eleven-month-old boy who was conditioned to fear furry objects in experiments conducted by American psychologist John B. Watson (1920) to demonstrate that phobias are learned responses based on classical conditioning.

Telegram: @medical_k

www.konkur.in

Little Hans Sigmund Freud's famous case history of a 5-year-old boy with a phobia. The boy's fear of horses, instead of his father, helped him to avoid hating his father, by whom he was threatened; and whom he also loved.

living will Legal document in which patients gives instructions to their physicians about withholding life support measures, for example, Do Not Resuscitate (DNR) if in extremis.

LCME Liaison Committee on Medical Education.

LLPDD Late luteal phase dysphoric disorder.

LNNB Luria-Nebraska Neuropsychological Battery.

lobotomy Neurosurgical procedure, introduced by Egas Moniz, in which one or more nerve tracts in a lobe of the cerebrum are severed. Prefrontal lobotomy is the ablation of one or more nerve tracts in the prefrontal area of the brain and has been used in the treatment of certain severe mental disorders that do not respond to other treatments. Also called leukotomy.

localized amnesia Partial loss of memory; amnesia restricted to specific or isolated experiences. Also called lacunar amnesia; patch amnesia.

locus ceruleus Nucleus (a collection of neuronal cell bodies) that is located in the pons (a region of the brain stem) and contains the largest population of noradrenergic neurons in a single identified brain region; these neurons project their axons to virtually every region of the brain and are thought to be involved in the regulation of mood, anxiety, and attention.

logorrhea Copious, pressured, coherent speech; uncontrollable, excessive talking; observed in manic episodes of bipolar disorder. Also called tachylogia; verbomania; volubility.

logotherapy Existential analysis based on spiritual values, rather than psychobiologic laws.

longitudinal study Examination or analysis carried out of a long period of time.

long-term memory Reproduction, recognition, or recall of experiences or information that were experienced in the distant past. Also called remote memory. *Compare* immediate memory; short-term memory.

Telegram: @medical_k

www.konkur.in

loosening of associations Characteristic schizophrenic thinking or speech disturbance involving a disorder in the logical progression of thoughts, manifested as a failure to adequately verbally communicate; unrelated and unconnected ideas shift from one subject to another. *See also* tangentiality.

Lou Gehrig disease AMYOTROPHIC LATERAL SCLEROSIS.

LP Lumbar puncture.

LSD Lysergic acid diethylamide.

Lumbar puncture (LP) Use of a needle inserted into the lumbar spine intervertebral space to obtain cerebrospinal fluid for diagnostic purposes or to introduce local anesthetics or other drugs.

Luria-Nebraska Neuropsychological Battery (LNNB) Based on the work of the Russian psychologist A. R. Luria, the test assesses a wide range of cognitive functions: memory; motor functions; rhythm; tactile, auditory, and visual functions; receptive and expressive speech; writing; spelling; reading; and arithmetic. It is extremely sensitive for identifying specific types of problems (e.g., dyslexia, dyscalculia) rather than being limited to more global impressions of brain dysfunction; it also helps localize the various cortical zones that are involved in a particular function and is useful in establishing left or right cerebral dominance. The test is designed for persons at least 15 years of age; a children's version for use with 8 to 12 year olds is being developed.

lust dynamism Harry Stack Sullivan's term to describe clearly stated sexual desires and abilities.

lying Making statements that one knows consciously are false with intent to deceive; differentiated from confabulation, in which one is not conscious of lying.

lysergic acid diethylamide (LSD) A potent psychotogenic drug discovered in 1942 that produces psychotic-like symptoms and behavior changes, including hallucinations, delusions, and time-space distortions. Commonly called acid.

M

Telegram: @medical_k

www.konkur.in

macropsia False perception that objects are larger than they really are. *Compare* micropsia.

magical thinking A form of dereistic thought; thinking similar to that of the preoperational phase in children (Jean Piaget), in which thoughts, words, or actions assume power (e.g., to cause or to prevent events). Common in dreams, certain mental disorders, and children.

magnetic resonance imaging (MRI) Diagnostic modality in which a patient's body is placed in a magnetic field and its hydrogen nuclei are excited by radiofrequency pulses at angles to the field's axis; resulting signals from the body's hydrogen ions are processed through a computer to produce an image; an excellent method for differentiating gray and white matter, visualizing cerebrospinal fluid, and estimating the size of ventricles.

Mahler, Margaret (1897–1985) Hungarian-born psychiatrist and child analyst who described the separation–individuation process in children.

maintenance drug therapy Stage in the course of chemotherapy at which, after the drug has reached its maximal efficacy, the dosage is reduced and sustained at the minimal therapeutic level that will prevent a relapse or exacerbation.

major affective disorder *See* major depression.

major depressive disorder Severe mood disorder characterized by one or more depressive episodes but no history of a manic episode; a DSM-5 diagnosis. *See also* mood disorder.

major depressive episode, melancholic type DSM diagnosis replacing involutional melancholia.

major epilepsy *See* grand mal epilepsy.

major motor seizure *See* grand mal epilepsy.

major neurocognitive disorder DSM-5 term for dementia.

major tranquilizer ANTIPSYCHOTIC.

maladaptive Referring to any mental activity or behavior that is dysfunctional or counterproductive with regard to a person's ability to cope effectively with the problems and stresses of life.

Telegram: @medical_k

www.konkur.in

maladjustment Maladaptive reaction; poor, faulty, or inadequate coping ability.

male erectile disorder DSM sexual arousal disorder characterized by the recurrent and persistent partial or complete failure to obtain or maintain penile erection until the completion of the sex act. Also called erectile dysfunction. *See also* impotence.

male hypoactive sexual desire disorder Disorder characterized by an absence of or reduction in sexual fantasies and/or the desire for sexual activity in men

maleness Anatomic and physiologic features relating to the male's procreative functions.

malingering Feigning disease in order to achieve a specific goal, for example, to avoid an unpleasant responsibility. *Compare* factitious disorder.

malpractice Professional negligence including intentional or willful invasion of another's legally protected interests, such as battery or treatment without consent; must be demonstrated by the presence of *d*ereliction of a *d*uty *d*irectly causing *d*amages (the four D's of malpractice).

mania Mood abnormality characterized by elation; agitation; hyperactivity and hyperexcitability; accelerated thinking and speaking (flight of ideas); decreased need for sleep; and overinvolvement in pleasurable behavior. Characterizes the manic phase of bipolar I disorder when lasting more than a week or is severe enough to warrant hospitalization. *Compare* hypomania.

manic Denoting or characterized by mania. Sometimes used as a general description for a mentally disturbed person, often someone exhibiting violent or grossly irrational behavior.

manic–depressive illness Mood disorder characterized by severe alterations in mood that are usually episodic and recurrent. The unipolar type is characterized by either periodic episodes of mania (manic disorder) or periodic episodes of depression (depressive disorder). In the bipolar or circular type, the patient has at least one episode of each mood extreme and may alternate periodically between the two. Manic–depressive illness has been replaced by bipolar disorder in DSM.

Telegram: @medical_k

www.konkur.in

manifest content That part of a dream or fantasy that a person remembers and reports; in a dream, it represents a disguised and symbolic expression of the latent content of the dream.

manipulation Exploitativeness; the maneuvering by patients to get their own way, characteristic of antisocial personalities.

mannerism Stereotyped gesture or expression that is peculiar to a given person.

mantra In transcendental meditation, a Sanskrit syllable or word that is repeated over and over in an effort to produce total relaxation and control over one's state of consciousness.

MAOI Monoamine oxidase inhibitor.

marasmus Progressive emaciation, especially in malnourished infants and children, in which weight is often below the third percentile and markedly below appropriate weight for height.

marathon Technique developed by George Bach and Frederick Stoller that incorporates a group meeting that usually lasts 8 to 72 hours (although some may last for a week), in which the sessions interrupted only for eating and sleeping; the leader works for the development of intimacy and the open expression of feelings. The time-extended group experience culminates in intense feelings of excitement and elation.

marijuana Dried leaves and flowers of *Cannabis sativa* (Indian hemp), which induce somatic and psychic changes in a person when smoked or ingested in sufficient quantity. Somatic changes include increased heart rate, rise in blood pressure, dryness of the mouth, and increased appetite; psychic changes include a dreamy-state level of consciousness, a sense of enhanced vividness of visual and auditory sensations, disturbances of time perception and memory-dependent, goal-directed behavior, disruptions of sequential thought processes, and euphoria and other alterations of mood. The compound believed to be responsible for most of its psychological effects is tetrahydrocannabinol (THC). In strong doses, marijuana can produce hallucinations and, at times, paranoid ideation. Also called pot; grass; weed; dope; Mary Jane.

Telegram: @medical_k

www.konkur.in

marital counseling Process whereby a trained counselor helps married couples resolve problems that arise and trouble them in their relationship; the husband and the wife are seen by the same worker in separate and joint counseling sessions that focus on immediate family problems. The theory and techniques of this approach were first developed in social agencies as part of family case work.

marital problems Maladaptive behavior between spouses in various areas, for example, attitudes toward sex, contraception, child rearing, money handling.

marital therapy *See* marriage therapy.

marriage therapy Type of family therapy that involves the husband and the wife and focuses on the marital relationship as it affects the individual psychopathology of the partners. The rationale for the method is the assumption that psychopathologic processes within the family structure and in the social matrix of the marriage perpetuate individual pathologic personality structures, which find expression in the disturbed marriage and are aggravated by the feedback between partners.

masculine identity Inner sense of gender affiliation with males. *Compare* feminine identity.

masculine protest Adlerian doctrine that depicts a universal human tendency to move from a passive and feminine role to a masculine and active role; an extension of Alfred Adler's ideas about organic inferiority that became the prime motivational force in normal and neurotic behavior in his system. *See also* Adler, Alfred; inferiority complex.

masculinity–femininity scale Any scale on a psychological test that assesses the relative masculinity or femininity of the testee. Scales vary and may focus, for example, on basic identification with either sex or preference for a particular sex role and are strongly influenced by cultural definitions of masculinity and femininity.

masochism Paraphilia in which sexual gratification is derived from being physically or psychologically maltreated by a partner or oneself; first described by an Austrian novelist, Leopold von

Telegram: @medical_k

www.konkur.in

Sacher-Masoch (1836–1895). *See also* sadism; sadomasochistic relationship.

masturbation Self-stimulation of the genitals for sexual pleasure. *See* autoerotism.

maternal deprivation Result of the premature loss or absence of the mother. In a broader sense, the lack of proper mothering may constitute a form of maternal deprivation which may lead to severe emotional disorders in infants and children.

maturational crises Normative stages of the life cycle that require adaptive coping or defense mechanisms.

maximum security unit That part of an institution for the mentally ill reserved for those who have committed crimes or who are considered dangerous to others.

MCE Medical care evaluation.

MDMA 3,4-Methylenedioxymethamphetamine.

mean Statistical measurement derived from adding a set of scores and then dividing by the number of scores. *See also* average.

mean deviation Statistical measure of the variability in a set of values defined as the sum of the absolute differences between the values and the mean divided by the number of values.

median Value in a set of values above and below which there are an equal number of values; for example, in the series 1, 3, 5, 9, 33 the value 5 is the median. *See also* average.

Medicaid Assistance program for certain needy and low-income persons, mandated by the federal government and financed by both federal and state governments; certain benefits, such as in- and outpatient hospital care, physicians' services, and laboratory tests, are required covered expenses, while other services may be provided at the state's option.

medical audit Retrospective assessment of the quality and utilization of care, including investigation of suspected problems, analysis of the problems identified, and a plan for corrective action. Also called medical care evaluation (MCE).

medical care evaluation (MCE) MEDICAL AUDIT.

Telegram: @medical_k

www.konkur.in

medical ethics Moral set of principles that determine what is right or wrong and good or bad, as they pertain to professional responsibilities and opinions relating to the values of patients, patients' families, and society at large. For related issues, see the specific term.

medical record Written exposition describing a patient's diagnosis and treatment.

medical review Evaluation of the quality of care and assessment of medical care or services judged in terms of cost effectiveness.

Medicare Hospital and medical insurance system for the aged created in 1965 by amendments of the Social Security Act. Hospitalization in general hospitals for psychiatric conditions is covered in the same way as other conditions.

medication-induced movement disorders A group of disorders that include neuroleptic malignant syndrome, neuroleptic-induced parkinsonism, neuroleptic-induced acute akathisia, neuroleptic-induced tardive dyskinesia, neuroleptic-induced acute dystonia, and medication-induced postural tremor.

megalomania Morbid preoccupation with expansive delusions of power, importance, or wealth.

megavitamin therapy *See* orthomolecular treatment.

melancholia A severe depressive state characterized by anhedonia, early morning awakening, weight loss, psychomotor retardation, and profound feelings of guilt and hopelessness; often associated with suicidal ideation.

memory Process whereby what is experienced or learned is established as a record in the central nervous system (registration), where it persists with a variable degree of permanence (retention) and can be recollected or retrieved from storage at will (recall). For types of memory, see the specific term.

menarche Onset of menstrual function.

mendacity Pathologic lying.

mens rea Legal term meaning an intent to do harm.

mental aberration Pathologic deviation from normal thinking; unrelated to a person's intelligence.

Telegram: @medical_k

www.konkur.in

mental age Measure of mental ability as determined by standard psychological tests.

mental deficiency Term often used interchangeably with mental retardation, applied to individuals with an IQ of less than 70. *See* intellectual developmental disorder.

mental disorder, mental disease Psychiatric illness or disease whose manifestations are primarily characterized by behavioral or psychological impairment of function, measured in terms of deviation from some normative concept.

mental health State of emotional well-being in which persons are able to function comfortably within their society and in which their personal achievements and characteristics are satisfactory to them.

mental hygiene 1. Conditions and practices conducive to the establishment and maintenance of mental health. **2.** Field dealing with the prevention and early treatment of mental illness. *See also* orthopsychiatry.

mental illness Mental disorder; any serious impairment of adjustment; any psychiatric disorder listed in the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* or in the World Health Organization's *International Classification of Diseases.*

mental retardation Term previously assigned to the condition that DSM-5 now refers to as intellectual disability. Degrees of condition were historically classified according to IQ: mild (50–55 to 70), moderate (35–40 to 50–55), severe (20–25 to 30), and profound (below 20–25). *See* intellectual disability.

mental status General functional condition of mental and behavioral processes as determined by psychiatric assessment of a variety of areas of functioning, such as state of consciousness, mood and affect, thinking and speech, motor behavior, general knowledge, memory, calculation, judgment, abstraction, and insight.

mental status examination (MSE) Clinical evaluation, and the sum total of the examiner's observations and impressions, of a person's psychological and behavioral experiences. MSE includes specific references to such areas as attitude and general behavior

Telegram: @medical_k

www.konkur.in

during interview and to sensorium, mental capacity, and other areas of function.

merycism RUMINATION DISORDER OF INFANCY.

mescaline Hallucinogenic drug obtained from buttons of the peyote cactus that has psychotomimetic effects similar to those of LSD.

mesmerism Early term for hypnosis.

mesomorphic Muscular, with a well-proportioned physique; one of Sheldon's constitutional types. *Compare* ectomorphic; endomorphic.

meta-analysis General consensus of many studies that results in one common data base that helps to eliminate bias.

metapsychiatry Branch of psychiatry concerned with altered state of consciousness, holistic health, and parapsychology.

metapsychology Branch of theoretical or speculative psychology concerned with theories, hypotheses, or phenomena that are largely beyond the realm of empirical verification. *See also* parapsychology.

methadone Orally active synthetic narcotic agent that is an effective analgesic with pharmacologic actions qualitatively very similar to those of morphine. Its use in the maintenance treatment of heroin addicts is based on its extended duration of action in suppressing withdrawal symptoms in persons physically dependent on opiates.

methadone maintenance treatment *See* methadone.

3-methoxy-4-hydroxyphenylglycol (MHPG) Most significant metabolic product from central nervous system norepinephrine; excreted in urine.

3,4-methylenedioxymethamphetamine (MDMA) Hallucinogen more commonly known as ecstasy.

methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) Contaminant of an illicitly made synthetic heroin that induces irreversible parkinsonism.

metonymy Speech disturbance common in schizophrenia in which the affected person uses a word or phrase that is related to the proper one but is not the precise one that would ordinarily be used; for example, the patient speaks of consuming a "menu,"

Telegram: @medical_k

www.konkur.in

rather than a “meal,” or refers to losing the “piece of string” of the conversation, rather than the “thread” of the conversation. *See also* paraphasia; word approximation.

Metrazol treatment Obsolete form of convulsive therapy in which a convulsive seizure is induced by injection of the drug Metrazol (pentylenetetrazol).

Meyer, Adolf (1866–1950) American psychiatrist known for his concept of psychobiology and “commonsense” psychiatry.

MHPG 3-Methoxy-4-hydroxyphenylglycol.

microcephaly Condition in which the head is unusually small as a result of defective brain development and premature ossification of the skull.

micropsia False perception that objects are smaller than they really are. Sometimes called lilliputian hallucination. *Compare* macropsia.

MID Multi-infarct dementia.

middle age, middle adulthood That period considered to be the prime of life, between the ages of approximately 40 to 65 years, following the termination of early adulthood.

middle insomnia Waking up after falling asleep without difficulty and then having difficulty in falling asleep again. *Compare* initial insomnia; terminal insomnia.

midlife crisis Syndrome that occurs in both sexes as they enter their early 40s or 50s, consisting of depression, substance abuse, concern about growing old, and fear of death; more common in adults with prior psychiatric illness than in normal adults.

migraine Severe unilateral, throbbing headache that appears periodically, usually beginning during the teenage years and continuing to recur with diminishing frequency during advancing years. Classic migraine is a syndrome ushered in by a transient derangement of neurologic function, often a visual disturbance, followed by hemicranial headache, nausea, and vomiting, all of which last for anywhere from several hours to 1 or 2 days. Common migraine has the same character and time course but develops without any prodrome. Patients with migraine are

Telegram: @medical_k

www.konkur.in

typically described as tense, meticulous, hard-driving persons who appear to have a high frequency of associated emotional conflicts.

mild mental retardation *See* mental retardation.

mild neurocognitive disorder Mild decline in cognitive function that is differentiated from the normal cognitive changes associated with aging; memory is impaired for age and education, however, general cognitive function and activities of daily living remain intact. In DSM-5 diagnosed as mild neurocognitive disorder due to multiple etiologies or unspecified neurocognitive disorder.

milieu therapy Treatment that emphasizes appropriate socioenvironmental manipulation for the benefit of the patient; the setting is usually the psychiatric hospital. *See also* moral treatment; therapeutic community.

mimicry Simple, imitative motion activity of childhood.

minimal brain dysfunction Behavioral syndrome of childhood, now called attention-deficit hyperactivity disorder, characterized by learning difficulties, decreased attention span, distractibility, hyperactivity, impulsiveness, emotional lability, and, often, disturbances in perceptuomotor and language development; its psychopathologic mechanisms have not been defined. The term implies neurologic causation, but in most cases there are no major unequivocal neurologic signs and there has been a tendency to apply the term as a convenient explanatory label to any child presenting with a specific learning difficulty or behavioral dysfunction. Although the syndrome has been diagnosed with increasing frequency over the past 20 years, its validity as a diagnostic entity has been questioned, and it is not listed as such in DSM.

Minnesota Multiphasic Personality Inventory (MMPI) Questionnaire type of psychological test for persons age 16 and over consisting of true–false statements that are coded in various scales that assess different dimensions of the person's personality structure and measure the closeness of fit with various psychiatric diagnostic categories.

minor epilepsy PETIT MAL EPILEPSY.

Telegram: @medical_k

www.konkur.in

minor tranquilizer ANXIOLYTIC.

Mitchell, S. Weir (1830–1914) American neurologist known for his concept of rest treatment to cure emotional disorders.

mixoscopia Sexual perversion in which a person attains orgasm by watching their love object make love with another person.

MMPI Minnesota Multiphasic Personality Inventory.

M'Naghten rule Set of rules established in 1843 in England to determine criminal responsibility, based on the person's ability to distinguish right from wrong. *See also* Durham rule; American Law Institute formulation of insanity.

mode In a set of measurements, the value that appears most frequently. *See also* average.

modeling Learning of a new skill or behavior by observation and imitation of another person.

Model Penal Code American Law Institute's test of criminal responsibility: "A person is not responsible for criminal conduct if at the time of such conduct, as a result of mental disease or defect, he lacked substantial capacity to either appreciate the criminality (wrongfulness) of his conduct or to conform his conduct to the requirement of the law."

moderate mental retardation *See* mental retardation.

molecular psychiatry Etiologic view of psychiatry based on neurotransmitter chemicals as measured in molecular quantities.

mongolism Obsolete and culturally offensive term for Down syndrome.

monoamine Biogenic amine or class of neurotransmitters that consists of three catecholamines (dopamine, norepinephrine, and epinephrine), an indolamine (serotonin), a quaternary amine (acetylcholine), and an ethylamine (histamine).

monoamine oxidase (MAO) Enzyme that deaminates monoamines and that functions, in the nervous system by breaking down monoamine neurotransmitters (e.g., norepinephrine, epinephrine, dopamine, and serotonin); has been subdivided into Type A and Type B.

Telegram: @medical_k

www.konkur.in

monoamine oxidase inhibitor (MAOI) Agent that inhibits the enzyme monoamine oxidase (MAO). MAO inhibitors are highly effective as antidepressants and are also used in the treatment of panic disorders and some eating disorders.

monomania Morbid mental state characterized by preoccupation with one subject. Also called partial insanity.

monosymptomatic hypochondriacal psychosis A delusional disorder consisting of somatic delusions; common delusions include infestation, dysmorphophobia, and foul body odors or halitosis.

monozygotic twins Twins who develop from a single fertilized ovum. In contrast, dizygotic or fraternal twins develop from two separately fertilized ova. Also called identical twins.

mood Pervasive and sustained feeling tone that is experienced internally and that, in the extreme, can markedly influence virtually all aspects of a person's behavior and their perception of the world. Distinguished from affect, the external expression of the internal feeling tone. For types of mood, see the specific term.

mood-congruent delusion Delusion with content that is mood appropriate, for example, a depressed patient who believes they are responsible for the destruction of the world.

mood-congruent hallucination Hallucination with content that is consistent with either a depressed or a manic mood, for example, a depressed patient hearing voices telling the patient they are a bad person; a manic patient hearing voices telling the patient they have inflated worth, power, or knowledge.

mood-congruent psychotic features DSM term that refers to hallucinatory or delusional phenomena with contents that consistently reflect the mood of a manic or depressed patient.

mood disorders Qualitative terms used to describe the striking symptomatic features or timing patterns in various patients with moods disorders. Descriptive qualifiers include psychotic, melancholic, atypical, and catatonic features; patterns include postpartum onset, rapid cycling, and seasonal pattern.

mood-incongruent delusion Delusion based on incorrect reference about external reality, with content that has no association to mood

Telegram: @medical_k

www.konkur.in

or is mood-inappropriate, for example, a depressed patient who believes they are the new Messiah.

mood-incongruent hallucination Hallucination not associated with real external stimuli, with content that is not consistent with either depressed or manic mood, for example, in depression, hallucinations not involving such themes as guilt, deserved punishment, or inadequacy; in mania, not involving such themes as inflated worth or power.

mood-incongruent psychotic features DSM term that refers to hallucinatory or delusional phenomena with contents that do not consistently reflect the mood of a manic or depressed patient.

mood stabilizer Drug used to prevent mood swings in bipolar disorder.

mood swing Oscillation of a person's emotional feeling tone between periods of elation and periods of depression.

moral treatment Philosophy and technique of treating mental patients, developed in the 18th century, that involved the establishment of a humane therapeutic environment designed to maximize the chances for recovery; considered the forerunner of current milieu therapy.

morbid jealousy Marked or severe jealousy. Also called pathologic jealousy.

morbid perplexity Condition seen in schizophrenia in association with loss of ego boundaries; the patient exhibits profound confusion about his own identity and the meaning of existence.

moron Obsolete and pejorative term for a classification of mental retardation in which an individual has a mental age of approximately 8 years.

morphine Major phenanthrene alkaloid opium derivative that produces a combination of central nervous system excitation and depression; repeated administration can lead to tolerance, physical dependence, and psychological dependence; used as an analgesic, sedative, and anxiolytic.

Moses and Monotheism Title of a book by Sigmund Freud (1939) in which he undertook a historical but frankly speculative reconstruction of the personality of Moses and examined the

Telegram: @medical_k

www.konkur.in

concept of monotheism and the abiding effect of the patriarch on the character of the Jews; one of Freud's last works, it bears the imprint of his latter-day outlook and problems.

mother surrogate In psychoanalysis, a mother substitute onto whom a patient projects their mother image and responds to unconsciously, in an inappropriate and unrealistic manner, with the feelings and attitudes that they had toward the real mother.

motivation Force or energy associated with an internal state that propels a person to engage in behavior to satisfy a need or desire.

motor aphasia Aphasia in which understanding is intact but the ability to speak is lost. Also called Broca's, expressive, or nonfluent aphasia.

motor disorders A class of neurodevelopmental disorders defined by a delay in meeting expected milestones for motor skills, based on age and intelligence, which significantly impairs daily functioning. The major types of motor disorders include developmental coordination disorder, stereotypic movement disorder, and tic disorder.

mourning Syndrome following loss of a loved one, consisting of preoccupation with the lost individual, weeping, sadness, and repeated reliving of memories. *See also* bereavement; grief.

MPD Multiple personality disorder.

MPTP Methyl-4-phenyl-1,2,3,6-tetrahydropyridine.

MRI Magnetic resonance imaging.

multi-infarct dementia *See* vascular dementia.

multiple delusions Concurrent delusions in which the delusions need not be interconnected.

multiple personality disorder *See* dissociative identity disorder.

multiple regression Multivariate analysis in which a scaled variable is correlated with a linear combination of independent or predictor variables.

multiple therapy CO-THERAPY.

multivariate analysis Methods for considering the relationship of three or more variables, including multiple regression, multivariate

Telegram: @medical_k

www.konkur.in

analysis of variance, discriminant analysis, canonical correlation, and factor analysis.

Munchausen syndrome Alternate term for factitious disorder.

muscarine Naturally occurring alkaloid found in certain species of poisonous mushrooms; symptoms of mushroom poisoning develop within 30 minutes of ingestion and consist of vomiting, diarrhea, bronchospasm, hypertension, delirium, and shock.

mutism Organic or functional absence of the faculty of speech. *See also* stupor.

mydriasis Dilation of the pupil; sometimes occurs as an autonomic (anticholinergic) side effect of some phenothiazines and tricyclic antidepressant drugs.

mysophobia Abnormal fear of dirt or contamination.

N

naloxone Opiate antagonist that, unlike nalorphine which it has largely replaced as a narcotic antagonist is essentially devoid of agonist effects. In opioid-dependent persons, small doses of naloxone precipitate moderate to severe withdrawal symptoms, an effect that can be used to diagnose physical dependence on narcotic drugs; however, the most important use of naloxone is in the treatment of narcotic overdosage. (Trade name, Narcan.)

NAMI National Alliance for the Mentally Ill.

narcissism Self-love linked to autoerotism but devoid of geniality. In psychoanalytic theory, it is divided into primary and secondary types: primary narcissism, the early infantile phase of object relationship development, when the child has not differentiated the self from the outside world and all sources of pleasure are unrealistically recognized as coming from within the self, giving the child a false sense of omnipotence; secondary narcissism, when the libido, once attached to external love objects, is redirected back to the self. *See also* autistic thinking.

narcissistic personality disorder Personality disorder characterized by a grandiose sense of self-importance, preoccupation with fantasies of unlimited success, exhibitionistic

Telegram: @medical_k

www.konkur.in

need for attention and admiration, exaggerated responses to criticism or other perceived threats to self-esteem, and disturbance in interpersonal relationships.

narcoanalysis NARCOTHERAPY.

narcolepsy Sleep disorder characterized by recurrent, brief, uncontrollable episodes of sleep; often associated with cataplexy. *See also* hypersomnia.

narcosis Drug-induced stupor.

narcosynthesis NARCOTHERAPY.

narcotherapy Psychotherapy conducted with the patient in a drug-induced stupor or semiconscious state, as by the administration of barbiturates; originally used in the treatment of acute disorders arising in the setting of military combat; also called narcoanalysis; narcosynthesis.

narcotic Any natural or synthetic drug producing morphine-like analgesia, drowsiness, mental clouding, and, with prolonged use, physical dependence. *See also* opioid.

narcotic blockade Inhibition of the euphoric effects of even high doses of intravenous opioids, such as heroin, by the use of other drugs, such as methadone.

National Alliance for the Mentally Ill (NAMI) Self-help group and influential national advocacy network comprised of and supported by the family members and parents of schizophrenic patients.

National Board of Medical Examiners (NBME) National board, founded in 1915, for testing medical students by three examinations given during different stages of their medical education to qualify for licensure to practice medicine in the United States; the diploma is accepted in 50 states for obtaining licensure without further examination by the state.

National Center for Complementary and Alternative Medicine (NCAAM) A government agency, part of the National Institute of Health that tests and evaluated alternative medicine therapies, for example, nutritional supplements, prayer, yoga, among many others.

Telegram: @medical_k

www.konkur.in

National Institute of Alcohol Abuse and Alcoholism (NIAAA) *See* Alcohol, Drug Abuse, and Mental Health Administration.

National Institute of Drug Abuse (NIDA) *See* Alcohol, Drug Abuse, and Mental Health Administration.

National Institute of Mental Health (NIMH) *See* Alcohol, Drug Abuse, and Mental Health Administration.

National Mental Health Association (NMHA) Voluntary citizens' organization, founded in 1909 as the National Committee on Mental Hygiene, to promote mental health.

National Training Laboratories (NTL) Organization started in 1947 at Bethel, Maine, to train professionals who work with groups; interest in personal development eventually led to sensitivity training and encounter groups.

natural group Any group that tends to evolve spontaneously in human civilization, such as a kinship, tribal, or religious group in contrast to various contrived groups or aggregates of people who meet for a relatively brief time to achieve some goal.

NBME National Board of Medical Examiners.

NCAAM National Center for Complementary and Alternative Medicine.

necromania Pathologic preoccupation with dead bodies.

necrophilia Sexual attraction to or sexual contact with dead bodies.

necrophobia Abnormal fear of dead bodies.

need Ambiguous term referring to an internal state of unsatisfaction or tension related to a wish, urge, desire, or other endogenous behavioral stimulus; classically, it implied an innate or instinctual internal stimulus. *See also* drive; instinct; motivation.

needle phobia The persistent, intense, pathologic fear of receiving an injection.

negative reinforcement *See* reinforcement.

negative symptoms In schizophrenia: flat affect, alogia, abulia, and apathy.

negative transference *See* transference.

negativism Verbal or nonverbal opposition or resistance to outside suggestions and advice; commonly seen in schizophrenia in which

Telegram: @medical_k

www.konkur.in

the patient resists any effort to be moved or does the opposite of what is asked.

neologism New word or phrase whose derivation cannot be understood; often seen in schizophrenia. It has also been used to mean a word that has been incorrectly constructed but whose origins are nonetheless understandable (e.g., “headshoe” mean “hat”), but such constructions are more properly referred to as word approximations.

nervous breakdown Nonspecific lay term for mental disorder, often implying an acute decompensation.

neurasthenia Condition characterized by vague functional physical and mental fatigue; not used in DSM.

neurochemistry Branch of chemistry concerned with nervous system components, metabolism, and function.

neurocirculatory asthenia DA COSTA SYNDROME.

neuroendocrinology Subspecialty area concerned with the anatomical and functional relationships between the nervous system and the endocrine apparatus. *See also* psychoendocrinology.

neurohormone Chemical messengers formed by neurosecretory cells and released into the bloodstream.

neuroleptic drug ANTIPSYCHOTIC.

neuroleptic malignant syndrome (NMS) Life-threatening complication of antipsychotic treatment, including such symptoms as muscle rigidity and dystonia, akinesia, mutism, obtundation, and agitation.

neurologic amnesia **1.** Auditory amnesia: loss of ability to comprehend sounds or speech. *See also* Wernicke aphasia. **2.** Tactile amnesia: loss of ability to judge the shape of objects by touch. *See also* astereognosis. **3.** Verbal amnesia: loss of ability to remember words. **4.** Visual amnesia: loss of ability to recall or recognize familiar objects or printed words.

neurologic disorders Disorders involving the organization and function of nervous tissue, including diseases of the peripheral

Telegram: @medical_k

www.konkur.in

nerves, the spinal cord, and the brain, which are based on organic pathology.

neurologist Physician who specializes in diseases of the nervous system.

neurology Medical specialty concerned with organic diseases of the nervous system.

neuron Nerve cell, consisting of cell body, dendrites, and neuroaxon, which is the basic functional unit of the nervous system.

neuronal plasticity Ability of the central nervous system to alter its functional organization; a capacity for change that serves as a mechanism to shape neuronal circuitry during development, to change the way information is processed, and to compensate for injury.

neurophysiology Physiology of the nervous system.

neuropsychiatry Medical specialty that combines psychiatry and neurology.

neuroreceptors Neuronal and other nervous tissue sites that are stimulated or inhibited by neurotransmitters and/or psychotropic drugs.

neuroscience Branch of the life sciences concerned with the anatomy, physiology, biochemistry, or molecular biology of nerves and nervous tissue and, especially, with their relation to behavior and learning.

neurosis Mental or psychiatric disorder characterized primarily by anxiety, which may either be directly experienced and dominate the clinical picture or be unconsciously controlled and modified by various psychological mechanisms to produce other subjectively distressing and ego-alien symptoms. Although neuroses are not accompanied by gross distortion of reality or severe personality disorganization, normal functioning is impaired by the person's symptoms; they have no organic basis, are relatively persistent, and are treatable. Also called psychoneurosis.

neurotic disorder *See* neurosis.

neurotic process Process in which unconscious conflict is expressed by neurotic symptoms or personality disturbance.

Telegram: @medical_k

www.konkur.in

neurotoxin Agent, such as an antibody, causing destruction to nervous tissue.

neurotransmitter Any specific chemical agent released by a presynaptic cell that, upon excitation, crosses the synapse to stimulate or inhibit the postsynaptic cell.

NIAAA National Institute of Alcohol Abuse and Alcoholism.

nicotine dependence Inability to control the use of and dependence on tobacco. Nicotine dependence and withdrawal are classified as disorders in DSM.

NIDA National Institute of Drug Abuse.

night eating syndrome Eating disorder characterized by the consumption of large amounts of food after dinner; generally associated with insomnia and a lack of daytime appetite. In DSM-5, included in "Other Specified Feeding or Eating Disorders."

night hospital Part-time hospital facility in which patients function in the outside world during the day but return to the hospital at night. *Compare* day hospital; weekend hospital.

nightmare Anxiety attack experienced while having terrifying or frightening dreams; characterized by mild anxiety, good recall of the dream, and mild autonomic reactions. *Compare* nightmare disorder; sleep terror disorder.

nightmare disorder Sleep disorder characterized by frequent nightmares and associated insomnia resulting from a fear of sleep.

night-terror SLEEP TERROR DISORDER.

nihilism Delusion of the nonexistence of the self or part of the self; also refers to an attitude of total rejection of established values or extreme skepticism regarding moral and value judgments.

nihilistic delusion Delusional disorder in which patients believe the world and everything related to it have ceased to exist.

NIMH National Institute of Mental Health.

nitrogen narcosis RAPTURE-OF-THE-DEEP SYNDROME.

NMS Neuroleptic malignant syndrome.

noesis Revelation in which immense illumination occurs in association with a sense that one has been chosen to lead and command. Can occur in manic or dissociative states.

Telegram: @medical_k

www.konkur.in

nominal aphasia Aphasia characterized by difficulty in giving the correct name of an object. *See also* anomia; amnestic aphasia.

nonaffective hallucination Hallucination whose content is apparently unrelated to either depression or elation. *Compare* illusion.

noncomplementary role *See* role.

noncompliance with medical treatment DSM category used when a patient does not cooperate with the physician in their medical care; motivated by denial of illness, by religious beliefs, or by decisions based on personal value judgments about the advantages and disadvantages of the proposed treatment.

nondirective approach Technique in which the therapist follows the lead of the patient in the interview, rather than introducing their own theories and directing the course of the interview; applied in both individual and group therapy.

nonfluent aphasia MOTOR APHASIA.

nonparametric Denoting statistical methods that do not require restrictive assumptions about population distributions.

nonreactive depression ENDOGENOUS DEPRESSION.

nonsuicidal self-injury A DSM-5 disorder in which the patient intentionally inflicts damage to their body to induce bruises, bleeding, or pain without suicidal ideation. Also called self-mutilation.

non–24-hour sleep–wake circadian rhythm disorder A sleep–wake disorder characterized by a circadian period that is not congruent with the external environment; common in the blind, visually impaired, and those with traumatic brain injury.

noradrenaline NOREPINEPHRINE.

norepinephrine Catecholamine neurotransmitter substance liberated by adrenergic postganglionic neurons of the sympathetic nervous system; the precursor of epinephrine present in the adrenal medulla and also found in many areas of the brain. A disturbance in its metabolism at important brain sites has been proposed as an important factor in the causation of mood disorders. Also called noradrenaline.

Telegram: @medical_k

www.konkur.in

normality In psychiatry, the absence of mental illness; that state of mental health about which there exists a scientific and professional consensus. The normal person has a sense of their own worth and maintains a confident and purposeful self-image.

nosology Science of the classification of diseases.

nosophobia PATHOPHOBIA.

not-for-profit hospital Any hospital not maintained for the purpose of monetary gain. *Compare* for-profit hospital.

not otherwise specified (NOS) Term used in previous editions of DSM to describe unusual or uncharacteristic variations of different mental disorders; for example, eating disorder NOS, tic disorder NOS, pervasive developmental disorder NOS.

NREM sleep Non-REM sleep consisting of four stages, based on EEG findings: stage 1: low amplitude, first frequency immediately after sleep begins; stage 2: cycles of 12 to 16 Hz called sleep spindles; stages 3 and 4: increased amplitude and slow frequency EEG changes. *Compare* REM sleep.

NTL National Training Laboratories.

nuclear family Immediate members of a family, including the parents and the children.

nuclear magnetic resonance (NMR) *See* magnetic resonance imaging.

null hypothesis Research term for the hypothetical assumption that any difference observed between two groups or conditions or between a particular group and the general population is purely accidental and due to chance alone. *See also* Type 1 error; Type 2 error.

nyctophobia Abnormal fear of darkness or of the night.

nymphomania Abnormal, excessive, insatiable desire in a female for sexual intercourse. *Compare* satyriasis.

O

objective tests Typically, pencil-and-paper tests based on specific items and questions and that yield numerical scores and profiles

Telegram: @medical_k

www.konkur.in

easily subjected to mathematical or statistical analysis; for example, Minnesota Multiphasic Personality Inventory (MMPI).

object permanence As described by Jean Piaget, the child's (birth to 2 years) ability to understand that objects have an existence independent of their involvement with the object; the child is able to maintain a mental image of a person or object even though it is not present and not visible.

object relation Emotional attachment formed between one person and another, as opposed to interest in and love for oneself.

OBS Organic brain syndrome.

OSA Obstructive sleep apnea syndrome.

obsession Persistent and recurrent idea, thought, or impulse that cannot be eliminated from consciousness by logic or reasoning; obsessions are involuntary and ego-dystonic. *See also* compulsion.

obsessional jealousy disorder Descriptive condition in which a person has persistent thoughts about infidelity in a partner or spouse; not a diagnosis in DSM-5.

obsessive-compulsive disorder (OCD) Neurotic disorder characterized by the persistent recurrence of obsessions and compulsions.

obsessive-compulsive personality Personality disorder characterized by perfectionism, overconscientiousness, and excessive inhibition with regard to self-expression and relaxation. Also called anancastic personality.

obstructive sleep apnea syndrome (OSA) A dyssomnia characterized by periods of functional obstruction of the upper airway during sleepy, resulting in degreases in oxygen, after which breathing (at least briefly) resumes normally.

occupational problem Maladaptive patterns related to work. For example, job dissatisfaction and uncertainties about career choices.

occupational psychiatry Area of psychiatry concerned with mental illness in industry, including the psychiatric aspects of absenteeism, vocational adjustment, operational fatigue, and accident proneness.

Telegram: @medical_k

www.konkur.in

occupational therapy Form of therapy in which the patient engages in useful, purposeful activities in a therapeutic social setting involving interaction with other patients and hospital personnel.

OCD Obsessive-compulsive disorder.

oedipal phase PHALLIC PHASE. *See also* Oedipus complex.

Oedipus complex Constellation of feelings, impulses, and conflicts in the developing child that concern sexual impulses and attraction toward the opposite-sex parent and aggressive, hostile, or envious feelings toward the same-sex parent; real or fantasied threats from the same-sex parent result in the repression of those feelings. Development of the Oedipus complex coincides with the phallic phase of psychosexual development; as one of Freud's most important concepts, the term was originally applied only to the male. *Compare* Electra complex.

olfactory hallucination Hallucination primarily involving smell or odors; most common in medical disorders, especially in the temporal lobe.

Olfactory reference syndrome Alternate term for monosymptomatic hypochondriacal psychosis with delusions of foul body odor.

oligophrenia Old term for mental retardation.

OMD Organic mental disorder.

OMS Organic mental syndrome.

onanism Coitus interruptus. Sometimes used interchangeably with masturbation.

oneiroid state Dream-like state in which a patient is deeply perplexed and not fully oriented in time and place.

ontogenetic Pertaining to the development of an individual person. *Compare* phylogenetic.

open hospital Mental hospital without locked doors or physical restraints.

operant behavior *See* conditioning.

operant conditioning *See* conditioning.

operational definition Means of defining a word so that it is scientifically measurable.

Telegram: @medical_k

www.konkur.in

opiate Morphine or other alkaloids derived from opium, an extractable product of the poppy plant *Papaver somniferum* or its variety, *P. album. See also* opioid.

opiate receptor Specific site on a neuronal cell surface that interacts with opiate drugs and mediates their pharmacologic actions; presumably, it also mediates the physiologic functions of endogenous opioids, such as the enkephalins and endorphins.

opioid Any chemical substance that has morphine-like pharmacologic activity; for example, narcotic analgesics, such as methadone and meperidine, and endogenous opioid peptides, the enkephalins and the endorphins. *See also* opiate.

opioid peptide Peptide that exerts morphine-like actions through interactions with opiate receptors; for example, endorphin, enkephalin.

oppositional defiant disorder Mental disorder of childhood characterized by pervasive negativism, continuous argumentativeness, and an unwillingness to comply with reasonable suggestions and persuasion.

oral dyskinesia *See* tardive dyskinesia.

oral phase Earliest stage in psychosexual development, which lasts through the first 18 months of life. During this period the oral zone is the center of the infant's needs, expression, and pleasurable erotic experiences; it has a strong influence on the organization and development of the child's psyche.

organic A term used in psychiatry to denote a structural change or a chemical imbalance in the brain to account for a mental disorder. The term is still in common use but is no longer part of the official DSM nomenclature. *See also* organic disorder.

organic anxiety syndrome Syndrome characterized by prominent, recurrent panic attacks or generalized anxiety attributable to some clearly defined organic factor; cognitive functioning may be adversely affected as a secondary phenomenon.

organic brain syndrome (OBS) ORGANIC MENTAL SYNDROME.

organic delusional disorder Disorder characterized by the presence of prominent delusions in a state of full wakefulness and

Telegram: @medical_k

www.konkur.in

alertness than can be attributed to some clearly defined organic factor.

organic disorder Illness that is caused by structural or biochemical pathology. The term is not used in DSM but remains in common use. *Compare* functional disorder.

organic hallucinosis Disorder characterized by prominent or persistent hallucinations in a state of full wakefulness that can be attributed to some specific organic factor.

organic mental disorder (OMD) Mental disorder caused by transient or permanent brain dysfunction attributable to specific organic factors. In DSM, the organic mental disorders include dementias arising in the senium and presenium, psychoactive substance-induced organic mental disorders, and organic disorders associated with Axis III physical disorders or conditions or whose etiology is unknown. Also called organic psychosis.

organic mental syndrome (OMS) Psychological or behavior abnormality associated with transient or permanent dysfunction of the brain of unknown or unspecified etiology. OMS is characterized by a combination of disorientation to time, place, or person; signs of psychosis, for example, hallucinations or delusions; and impaired judgment and impulse control. The organic mental syndromes include delirium, dementia, amnestic syndrome, organic delusional syndrome, organic hallucinosis, organic mood syndrome, organic anxiety syndrome, organic personality syndrome, intoxication, and withdrawal; if the cause is known, the condition is called organic mental disorder. Also called organic brain syndrome. Both terms are considered obsolete given their implied mind-brain dichotomy.

organic mood syndrome Obsolete disorder characterized by either a depressive or a manic mood attributed to a clearly organic factor.

organic personality syndrome Term for frontal lobe syndrome.

organic psychosis ORGANIC MENTAL DISORDER.

orgasm Sexual climax, the peak psychophysiologic reaction to sexual stimulation.

Telegram: @medical_k

www.konkur.in

orgasm disorders One of the major categories of sexual dysfunctions. Characterized by the recurrent and persistent inability to achieve orgasm. Also called orgasmic dysfunction.

orgasmic phase Stage in the human sexual response cycle, as described by Masters and Johnson, in which orgasm occurs.

orgasmic platform Outer third of the vagina, which displays marked vasocongestion and contraction in the plateau phase of the female sexual response cycle, as described by Masters and Johnson.

orientation State of awareness of oneself and one's surroundings in terms of time, place, and person.

original thirteen *See* American Psychiatric Association.

orphan drug Any pharmacologic agent that is not economical to produce because the condition for which it is indicated affects relatively few persons.

Othello syndrome Eponym for conjugal paranoia.

orthomolecular psychiatry Theoretical school of thought proposing that psychiatric illnesses are due to biochemical abnormalities that result in increased requirements for specific substances, such as vitamins.

orthomolecular treatment Treatment that entails administration to psychiatric patients of large doses (megadoses) of vitamins (megavitamin therapy), trace elements, or other substances.

orthopsychiatry Interdisciplinary approach to the study and practice of maintaining or restoring mental health, involving principles derived from psychiatry, psychology, sociology, social work, medicine, and other fields; particular emphasis is placed on preventive techniques to promote healthy emotional development and growth, especially mental hygiene.

orthostatic hypotension Reduction in blood pressure brought about by a shift from a recumbent position to an upright position; observed as a side effect of several psychotropic drugs.

other-directed person Person who is readily influenced and guided by the attitudes and values of other people. *Compare* inner-directed person.

other interpersonal problems DSM category describing problems between one or more persons that cause sufficient strain to bring

Telegram: @medical_k

www.konkur.in

a person into contact with the mental health care system; the stress-inducing circumstances, coping mechanism, and symptoms that have brought someone to seek consultation or treatment must be individually evaluated.

other specified family circumstance DSM category used when the focus of attention or treatment is not due to a mental disorder or a parent–child or marital problem; may involve in-laws, grandparents, or other family members.

outcome variable DEPENDENT VARIABLE.

outpatient Ambulatory patient receiving medical care who does not require hospitalization.

ovarian dysgenesis TURNER SYNDROME.

overactivity Abnormality in motor behavior that can manifest itself as psychomotor agitation, hyperactivity (hyperkinesis), tics, sleepwalking, or compulsions.

overanxious disorder Anxiety disorder of childhood or adolescence characterized by excessive worrying and fearful behavior grossly disproportionate to the magnitude of the real environmental stress or threat.

overcompensation Conscious or unconscious exaggerated correction or compensation for a real or imagined physical or psychological deficit.

overdetermination Concept that phenomena such as dreams and neurotic symptoms reflect the operation of multiple causative factors, particularly with regard to symbolic meaning or significance.

overt homosexuality Behaviorally expressed homosexuality, as distinct from unexpressed conscious or unconscious homoerotic wishes that are held in check (latent homosexuality).

overvalued idea False or unreasonable belief or idea that is sustained beyond the bounds of reason. It is held with less intensity or duration than a delusion but is usually associated with mental illness.

P

Telegram: @medical_k

www.konkur.in

pain disorder Disorder characterized by multiple, recurrent pain complaints with no apparent physical cause; symptoms are linked to psychological factors. Pain disorder is a variant of somatic symptom disorder in which pain symptoms are the predominant physical complaints. The field of pain medicine encompasses pain linked to both psychological and/or organic factors.

Pain–pleasure principle Psychoanalytic concept which states that, in psychic functioning, a person tends to seek pleasure and avoid pain. *See also* pleasure principle.

panic Acute, intense attack of anxiety associated with personality disorganization; the anxiety is overwhelming and accompanied by feelings of impending doom.

panic attack Episode of acute intense anxiety occurring in panic disorder, schizophrenia, major depression, and somatization disorder.

panic disorder DSM classification of anxiety disorder characterized by attacks of acute intense anxiety, with or without agoraphobia.

panphobia Overwhelming fear of everything.

pantomime Gesticulation; psychodrama without the use of words.

paradoxical sleep REM SLEEP.

paralogia EVASION.

paralysisagitans PARKINSONISM.

paralytic ileus Intestinal obstruction resulting from inhibition of bowel motility, a rare anticholinergic side effect of certain psychoactive drugs. Also called adynamic ileus.

parameter Way of measuring or describing an object or evaluating a subject.

parametric tests of significance Statistical methods used to estimate population parameters, such as the mean and standard deviation; use of these methods requires assumptions about the population characteristics, for example, that the variable under study is normally distributed within the population from which the sample is drawn.

paramnesia Disturbance of memory in which reality and fantasy are confused. It is observed in dreams and in certain types of

Telegram: @medical_k

www.konkur.in

schizophrenia and organic mental disorders; includes phenomena such as déjà vu and déjà entendu, which may occur occasionally in normal persons.

paranoia Rare psychiatric syndrome marked by the gradual development of a highly elaborate and complex delusional system, generally involving persecutory or grandiose delusions, with few other signs of personality disorganization or thought disorder.

paranoiac Person with paranoia.

paranoid delusion Includes persecutory delusions and delusions of reference, control, and grandeur.

paranoid disorder *See* delusional disorder.

paranoid ideation Thinking dominated by suspicious, persecutory, or grandiose content of less than delusional proportions.

paranoid personality disorder Personality disorder characterized by rigidity, hypersensitivity, unwarranted suspicion, jealousy, envy, an exaggerated sense of self-importance, and a tendency to blame and ascribe evil motives to others.

paranoid schizophrenia Type of schizophrenia characterized by the presence of persecutory or grandiose delusions, often accompanied by hallucinations; no longer included in DSM-5.

paraphasia Abnormal speech in which one word is substituted for another, the irrelevant word generally resembling the required one in its morphology, meaning, or phonetic composition; the inappropriate word may be either a legitimate one used incorrectly, such as “clover” instead of “hand,” or a bizarre nonsense expression, such as “treen” instead of “train.” Paraphasic speech may be seen in organic aphasias and in mental disorders, such as schizophrenia. *See also* metonymy; word approximation.

paraphilia Psychosexual disorder with a sexual dysfunction characterized by persistent and recurrent sexual fantasies, often of an unusual nature, without which imagery erotic arousal or orgasm is not attained; fantasies generally involve themes of suffering, humiliation, sexual activity with nonconsenting partners, or preference for a nonhuman object for sexual arousal. In DSM, the paraphilias include fetishistic disorder, transvestic disorder, frotteuristic disorder, pedophilic disorder, exhibitionistic disorder,

Telegram: @medical_k

www.konkur.in

voyeuristic disorder, sexual masochism disorder, and sexual sadism disorder. Also called sexual deviations.

paraphrenia Chronic condition characterized by fantastic and absurd delusions without significant personality deterioration and without the primary disturbances of thought and affect that characterize schizophrenia.

parapraxis Faulty act, such as a slip of the misplacement of an article. Freud ascribed parapraxes to unconscious motives.

paraprofessional Trained person who works in a mental hospital and may have a degree in the arts or from some professional school other than those serving the mental health group but has not obtained a degree in one of the usual mental health professions.

parapsychology Branch of psychology concerned with extranormal events and behavioral phenomena not accounted for or explained by the tenets and laws of contemporary science; for example, clairvoyance, telepathy, psychokinesis. *See also* metapsychology.

parasomnias A group of dysfunctions associated with sleep, sleep stages, or partial arousals characterized by unusual behavior, experiences, or physiologic events during sleep; composed of the three subtypes: non-REM movement sleep arousal disorders (incomplete awakening accompanied by sleepwalking, sleep-related eating, sleep-related sexual behavior, or sleep terror disorder); REM sleep behavior disorder (vocal or motor behavior during sleep); and nightmare disorder.

parasympathetic nervous system *See* autonomic nervous system.

parataxic distortion Harry Stack Sullivan's term for distortions in judgment or attitude in interpersonal relations based on patterns set by earlier experience; previously developed ways of coping with significant people in a person's life are applied by the person in later interpersonal integrations.

parens patriae Power of the state to involuntarily hospitalize mentally ill persons in need of care; also called "police power," in that it prevents mentally ill persons from doing harm to themselves or to others.

Telegram: @medical_k

www.konkur.in

Parent–child problem DSM category that refers to problems between a parent and a child; for example, in a family in which the parents are divorced, with either the custodial or the noncustodial parent, and in the remarriage of a divorced or widowed parent.

paresis Weakness or partial paralysis of organic origin.

paresthesia Abnormal spontaneous tactile sensation, such as a burning, tingling, or pins-and-needles sensation.

peripartum depression Depressed mood, anxiety, insomnia, and weight changes that occur near parturition or within 1 month of giving birth. Previously called postpartum depression.

parkinsonism Extrapyramidal dyskinesia characterized by resting tremor, rigidity, bradykinesia, and postural abnormalities. Parkinsonism is of unknown etiology and occurs in middle or late life, typically with a gradual progression and a prolonged course. Also called paralysis agitans; Parkinson disease; idiopathic parkinsonism. A parkinsonian syndrome may develop during the course of therapy with antipsychotic phenothiazine or butyrophenone drugs; such drug-induced parkinsonism is reversible when the causative drug is withdrawn or its dosage reduced.

Parkinson disease PARKINSONISM.

partial hospitalization System of treating mental illness in which the patient is hospitalized on a part-time basis. *See also* day hospital; night hospital; weekend hospital.

partial insanity MONOMANIA.

passive–aggressive personality disorder Personality disorder in which the patient manifests aggressive behavior in passive ways, such as obstructionism, pouting, stubbornness, and intentional inefficiency.

passive-dependent personality *See* dependent personality disorder.

pastoral counseling Use of psychotherapeutic principles by a clergyman in helping parishoners with emotional problems.

patch amnesia LOCALIZED AMNESIA.

Telegram: @medical_k

www.konkur.in

pathognomonic Denoting a sign or symptom specifically diagnostic of a particular disease entity.

pathologic gambling Compulsion to gamble, one of the disorders of impulse control. *See also* gambling disorder.

pathologic intoxication ALCOHOL IDIOSYNCRATIC INTOXICATION.

pathophobia Abnormal fear of disease or suffering. Also called nosophobia.

paucity of speech Limited use of speech, seen in various pathologic states.

pavlovian conditioning CLASSICAL CONDITIONING. *See* conditioning.

Pavlov, Ivan Petrovich (1849–1936) Russian neurophysiologist famous for his work in conditioning.

pavor nocturnus SLEEP TERROR DISORDER.

PCP Phencyclidine.

peccatophobia Abnormal fear of sinning.

pecking order Hierarchy or sequence of authority in an organization or social group.

pederasty Anal intercourse between a man and a boy.

pedophilia Paraphilia in which a child is the sexual object.

pedophobia Abnormal fear of children.

peer review Review of physician services by a panel of other physicians.

Peer Review Organization (PRO) Federal review organization for hospitals receiving Medicare funds. In order to promote compliance with federal guidelines for health and hospital care, the PRO conducts independent utilization reviews and quality-of-care studies, validates diagnostic-related group (DRG) assignments, and reviews hospital admissions and readmissions. *See also* Professional Standards Review Organization; utilization review committee.

pellagra Deficiency of niacin (nicotinamide) characterized by diarrhea, dermatitis, and mental disturbance.

penis envy Sigmund Freud's concept that the woman envies the man for his possession of a penis; sometimes used to refer to a

Telegram: @medical_k

www.konkur.in

woman's generalized envy of men. A controversial concept given its heteronormative and patriarchal assumptions.

perception Conscious awareness of elements in the environment by the mental processing of sensory stimuli; sometimes used in a broader sense to refer to the mental process by which all kinds of data, intellectual, emotional, as well as sensory, are meaningfully organized. *See also* apperception.

perfectionism Practice of demanding of others or of oneself a higher quality of performance than is required by the situation.

period prevalence Research term for the total number of cases of a disease known to have existed during a specified time period. *Compare* point prevalence.

perseveration 1. Pathologic repetition of the same response to different stimuli, as in a repetition of the same verbal response to different questions. **2.** Persistent repetition of specific words or concepts in the process of speaking. Seen in organic mental disorders, schizophrenia, and other mental illness. *See also* verbigeration.

persistence Term used to reflect a personality trait characterized by ambition, overachievement, resistance to frustration, and fatigue. Persistence may be enhanced by psychostimulants.

persistent (chronic) motor or vocal tic disorder A type of motor disorder consisting of either motor or vocal tics, but not both, that develops before adulthood. Compare Tourette disorder.

persistent complex bereavement disorder Disorder characterized by chronic and persistent grief about the death of someone close to the patient, accompanied by feelings of bitterness, anger, or ambivalence toward the deceased and social withdrawal. Also known as complicated grief or complicated bereavement.

persona In Jungian psychology, the outside personality that a person presents to the world, as opposed to their inner self (anima).

personality Characteristic configuration of behavior response patterns that each person evolves as a reflection of their individual adjustment to life.

Telegram: @medical_k

www.konkur.in

personality disorder Mental disorder characterized by inflexible, deeply ingrained, maladaptive patterns of adjustment to life that cause either subjective distress or significant impairment of adaptive functioning; manifestations are generally recognizable in adolescence or earlier. Personality disorders listed in DSM include paranoid, schizoid, schizotypal, histrionic, narcissistic, antisocial, borderline, avoidant, dependent, and obsessive-compulsive.

personality traits Descriptive features of an individual's personality that are within normal limits.

persuasion Supportive psychotherapy in which the patient is encouraged to follow advice; persuasion is directive and limited in its goals.

pervasive developmental disorder Class of developmental disorders characterized by severe distortions in social skills, language, and contact with reality (e.g., autism spectrum disorder). Many psychological functions are deficient, and a child with this type of disorder displays abnormalities that are not normal for any stage of development. This condition was previously known as childhood schizophrenia. In DSM-5, Asperger syndrome, Rett syndrome, and childhood disintegrative disorder are types of pervasive developmental disorders. *Compare* specific learning disorder.

pervasive developmental disorder not otherwise specified A diagnostic category used in DSM-5 to refer to pervasive developmental disorders that may have contradictory features and/or lack sufficient findings to meet full criteria for one of the other pervasive developmental disorders (autism, Asperger syndrome, Rett syndrome, childhood disintegrative disorder).

perversion Deviation from the expected norm. In psychiatry it commonly signifies sexual perversion. *See also* psychosexual disorder.

perverted logic EVASION.

PET Positron emission tomography.

petit mal epilepsy Epileptic disorder characterized by recurrent minor, nonconvulsive, momentary lapses of consciousness,

Telegram: @medical_k

www.konkur.in

commonly beginning in childhood and having a self-limited course. A typical attack involves a sudden transient loss of contact with the environment, during which the patient develops a dazed expression and pauses in what he is doing; this type of seizure has a classical electroencephalographic representation consisting of synchronous, symmetrical spike-and-wave discharges at 3 per second, without cortical localization. Also called absence epilepsy; minor epilepsy.

phallic overbearance Domination of another person by aggressive means; generally associated with masculinity in its negative aspects.

phallic phase Third stage in psychosexual development, following the anal stage and lasting from about age 2 or 3 to about age 6; resolution of the Oedipus complex is the dominant developmental conflict during this stage. During this period, sexual interest, curiosity, and pleasurable experiences are centered on the penis in boys and the clitoris in girls. Also called oedipal phase.

phantasy Alternative spelling of fantasy.

phantom limb False sensation that an extremity that has been lost is in fact present.

pharmacokinetics Way in which the body processes a drug; its principal divisions are drug absorption, distribution, metabolism, and excretion.

pharmacotherapy PSYCHOPHARMACOLOGY.

phase of life problem DSM category that refers to problems not severe enough to warrant a psychiatric diagnosis but that interfere with functioning, as arising from marriage, work, change in job, culture shock.

phencyclidine (PCP) Substance of abuse with effects similar to hallucinogens. Also called angel dust.

phenomenology Study of events or happenings in their own right, rather than from the point of view of inferred causes; associated with existential psychiatry and reflects the theory that behavior is determined by the way the person perceives reality, rather than by external reality in objective terms.

Telegram: @medical_k

www.konkur.in

phenothiazine One of a class of psychotropic drugs, the prototype of which is chlorpromazine, which are effective in the treatment of psychoses, especially schizophrenia; they exert a favorable influence with regard to the fundamental symptoms of schizophrenia as well as the secondary or accessory symptoms. Their mechanism of action may be related to the blockade of dopamine receptors at critical sites in the central nervous system.

phenotype Outward, observable expression of a person's genetic constitution. *Compare* genotype.

phenylketonuria (PKU) Genetic metabolic disorder characterized by the inability to convert the amino acid phenylalanine to tyrosine. If untreated, severe mental retardation results from the accumulation of large concentrations of toxic phenylketones; when detected early in infancy, the condition is treatable by the elimination of phenylalanine from the diet.

phenylpyruvic oligophrenia Former name for phenylketonuria.

pheromone Chemical signal that a person releases into the external environment and that affects the behavior or physiologic states of other persons.

phobia Persistent, pathologic, unrealistic, intense fear of an objector situation; the phobic person may realize that the fear is irrational but is, nonetheless, unable to dispel it. Some examples are: acarophobia (small objects), acrophobia (high places), agoraphobia (open places, leaving familiar setting of home), aichmophobia (pointed objects), ailurophobia (cats), algophobia (pain), androphobia (men), astraphobia or astrapophobia (thunder and lightning), autophobia (being alone, or of self), bathophobia (depths), claustrophobia (closed or confined places), coprophobia (excreta), cynophobia (dogs), demophobia (crowds), erythrophobia (blushing), gynophobia (women), haphephobia (being touched), hematophobia (sight of blood), hydrophobia (water), hypnophobia (sleep), lalophobia or glossophobia (speaking), mysophobia (dirt, contamination), necrophobia (dead bodies), nyctophobia (darkness, night), panphobia (everything), pathophobia or nosophobia (disease, suffering), peccatophobia (sinning), pedophobia (children), phonophobia (speaking aloud),

Telegram: @medical_k

www.konkur.in

photophobia (strong light), sitophobia (eating), taphophobia (being buried alive), thanatophobia (death), toxophobia (being poisoned), xenophobia (strangers), zoophobia (animals).

phobic disorder Frequent disorder characterized by a specific fear, which may represent a temptation, a punishment for the forbidden impulse, or a combination of both.

phobic neurosis PHOBIC DISORDER.

phonologic disorder *See* developmental articulation disorder.

phonophobia Abnormal fear of speaking aloud.

photophobia Abnormal fear of strong light.

phrenology Study of the bony conformation of the skull in the now discredited belief that it related to mental faculties and traits.

phylogenetic Pertaining to the development of the species. *Compare* ontogenetic.

physical dependence *See* drug dependence.

physical disorder Disorder of body function whose manifestations are not primarily behavioral or psychological.

Piaget, Jean (1896–1980) Swiss psychologist noted for his research on cognitive development in children; he divided the development of intelligence into three major periods: Sensorimotor (birth to 2 years), concrete operations (2 to 12 years), and formal operations (12 years through adult life).

piblokto Culture-specific syndrome seen in Eskimos, usually women, in which the affected person screams, cries, runs naked through the snow, sometimes with suicidal or homicidal tendencies.

pica Craving and eating of nonfood substances, such as paint and clay.

Pick disease *See* frontotemporal dementia.

pickwickian syndrome Condition characterized by obesity, hypoventilation, and hypersomnia.

Pinel, Phillipe (1746–1826) French reformer in the field of mental illness known for his work in abolishing physical restraints on hospitalized mental patients.

Telegram: @medical_k

www.konkur.in

piperazine Phenothiazine derivative with antipsychotic affects; for example, fluphenazine (Prolixin).

piperidine Phenothiazine derivative with antipsychotic effects; for example, thioridazine (Mellaril).

PKU Phenylketonuria.

placebo 1. Inactive substance or preparation that is given as though it were a pharmacologically active medicine; primarily used in controlled studies to determine the efficacy of medicinal preparations; any beneficial or deleterious effects of the placebo may be ascribed to psychological factors. **2.** Any type of treatment that has no specific effects on the particular illness involved.

placebo effect Phenomenon in which a person exhibits a clinically significant response to a pill containing a therapeutically inert substance or a treatment without specific effect on the person's condition. Placebo effects are not limited to subjective reports; physiologic functions may be objectively influenced.

plaques In psychiatry, pathologic masses of axons, neurons, and dendrites with a central amyloid core; associated with Alzheimer disease.

plasma level *See* blood level.

plasticity *See* neuronal plasticity.

plateau phase Stage in the human sexual response cycle, as described by Masters and Johnson, characterized by increased genital blood flow and sense of sexual excitement; it precedes orgasm.

play therapy Type of therapy used with children in which they reveal their problems on a fantasy level with dolls, clay, and other toys; the therapist intervenes opportunely with helpful explanations about the patient's responses and behavior in language geared to the child's comprehension. *See also* activity group therapy.

pleasure principle In psychoanalysis, the principle by which the id seeks immediate tension reduction by either direct or fantasied gratification; developmentally, the pleasure principle antedates the reality principle. Also called the pleasure-pain principle. *See also* reality principle.

Telegram: @medical_k

www.konkur.in

pleonexia Psychiatric disorder in which the patient has an excessive desire to acquire wealth or objects.

pluralism In psychiatry, the notion that multiple factors affect behavior.

PMDD Premenstrual dysphoric disorder.

point prevalence Research term for the total number of cases of a disease known to have existed at a given point in time. *Compare* period prevalence.

police power PARENS PATRIAE.

polygenic Involving the combined action or effects of several genes.

polymorphous perverse sexuality Psychoanalytic conceptualization of sexuality in the human infant, for whom sexual gratification can be achieved by homosexual, heterosexual, or inanimate stimulation of several body zones; all humans, therefore, have the potential to develop sexual perversions in adulthood, depending on how the sexual drives are channeled developmentally.

polyphagia Excessive eating. *See also* bulimia nervosa.

polysomnography Battery of tests that include an electroencephalogram, electrocardiogram, and electromyogram; often given with tests for penile tumescence, blood oxygen saturation, body movement, body temperature, galvanic skin response, and gastric acid. The tests are of assistance in a variety of conditions, such as insomnia, nocturnal myoclonus, sleep apnea, enuresis, somnambulism, seizure disorders, impotence, vascular headache, gastroesophageal reflux, and depression.

polysubstance dependence Disorder characterized by dependence on at least three categories of psychoactive substances.

polyuria Excessive excretion of urine.

population Research term for the entire collection of a set of objects.

porphyria Metabolic disorder characterized by excessive urinary excretion of porphyrins (pigments found in hemoglobin and certain cellular enzyme systems) or their precursors; mental symptoms

Telegram: @medical_k

www.konkur.in

are prominent in the form known as acute intermittent porphyria. Abdominal pain, constipation, and neuromuscular disturbances complete the clinical picture. Attacks may be precipitated by barbiturates.

positive reinforcement *See* reinforcement.

positive symptoms In schizophrenia: hallucinations, delusions, and thought disorder.

positive transference *See* transference.

positron emission tomography (PET) Imaging technique using short-lived positron-emitting elements of oxygen, carbon, and nitrogen used to label organic compounds (e.g., glucose, amino acids, and neurotransmitters), which are then introduced into the body by injection or inhalation; energy emitted is recorded by scintillation detectors and computer analyzed to construct and display images of transverse sections of tissues, such as the brain. Quantitative data can be assessed in specific areas for such functions as blood flow, oxygen or glucose metabolism, and other complex physiologic phenomena; alterations in metabolism associated with disease and the actions of medications can also be monitored in this way.

postpartum depression *See* peripartum depression.

postpartum psychosis A descriptive term for depressive or psychotic symptoms in women who have recently given birth; a subtype of bipolar disorder in DSM-5. Also called puerperal psychosis. *See also* peripartum depression.

posttraumatic stress disorder (PTSD) Anxiety disorder that occurs after and as a result of a major, disturbing, out of the ordinary event in a person's life, such as war or rape. The prominent symptoms of this disorder include nightmares, flashbacks, withdrawal, and hypervigilance; may have a delayed onset. *See also* acute stress disorder.

posturing Strange, fixed, and bizarre bodily positions held by a patient for an extended time. *See also* catatonia.

potency Male ability to perform the sexual act; specifically, the capacity to achieve and maintain an erection during coitus.

Telegram: @medical_k

www.konkur.in

poverty of content of speech Speech that is quantitatively adequate but qualitatively inadequate because it imparts minimal, vague, or repetitious information.

poverty of speech Restriction in the amount of speech used; replies may be monosyllabic. *See also* laconic speech.

PPO Preferred Provider Organization.

practice effect Research term referring to the improvement of performance in a task as a result of repeated trials.

Prader–Willi syndrome A developmental disability as a result of a small deletion involving chromosome 15. Symptoms include compulsive eating, obesity, intellectual disability, hypogonadism, small stature, hypotonia, and small hands and feet. Children also exhibit oppositional and defiant behavior.

preconscious One of three divisions of the psyche in Freud's topographic theory of the mind (the others being the conscious and unconscious), including all mental contents that are not in immediate awareness but that can be consciously recalled with effort.

predictive value Proportion of true-positive or true-negative tests; indicates what percentage of test outcomes are expected to coincide with assigned diagnoses.

predictor variable Test or score used to assess or predict future performance.

Preferred Provider Organization (PPO) Alternative delivery organization that employs a prospective payment system in which a corporation or insurance company forms an agreement with a particular group of community hospitals and doctors to supply health services to PPO members at a previously determined lower rate; patients enrolled in a PPO select their physicians and hospitals from among the list of participants.

prefrontal lobotomy *See* lobotomy.

pregenital stages In psychoanalysis, the first stages of psychosexual development (the oral and anal stages) that occur before the genitals have begun to exert the predominant influence on sexual behavior.

Telegram: @medical_k

www.konkur.in

prejudice Preconceived adverse judgment or opinion formed without just grounds or sufficient knowledge; elements of irrational suspicion or hatred are often involved, as in racial prejudice.

premature ejaculation Ejaculation occurring before or immediately after vaginal intromission during coitus; broader definitions take into consideration the ability of a male to delay ejaculation during coitus for a sufficient length of time to satisfy a normally responsive female partner.

premenstrual dysphoric disorder (PMDD) Depressive mood disorder characterized by irritability, emotional lability, headache, and anxiety or depression that occurs about 1 week before menses and resolves after the menstrual cycle is complete. Also called late luteal phase dysphoric disorder.

premorbid Occurring before the onset of disease.

preoccupation of thought Centering of thought content on a particular idea, associated with a strong affective tone, such as paranoid trend or a suicidal or homicidal preoccupation.

presenile dementia DEMENTIA OF THE ALZHEIMER TYPE; PRESENILE ONSET.

presenium Period preceding old age, generally ages 55 to 65.

pressure of speech, pressured speech Increase in the amount of spontaneous speech; rapid, loud, accelerated speech, as occurs in mania, schizophrenia, and cognitive disorders.

prevalence Total number of cases of a disease existing at a given point in time (point prevalence) or during a specified time period (period prevalence). *See also* incidence.

prevalence rate Number of diagnosed cases of a disease or a condition at a particular point in time; prevalence rate per 1,000 is defined as the cases at a specific point in time, divided by the number of persons in the population at a specific point in time, multiplied by 1,000.

preventive psychiatry Branch of preventive medicine concerned with mental disorders. Encompassed within its scope are measures to prevent mental disorders (primary prevention); measures to limit the severity of illness, as through early case

Telegram: @medical_k

www.konkur.in

finding and treatment (secondary prevention); and measures to reduce disability after a disorder (tertiary prevention).

primal father Hypothetical head of a tribe depicted by Sigmund Freud in *Totem and Taboo* as slain by his sons, who subsequently devour him in a cannibalistic rite; later, he is promoted to a god. The son who murders him is the prototype of the tragic hero, and the memory of the crime is perpetuated in the conscience of the individual and of the culture.

primal scene In psychoanalysis, the real or fantasied observation by a child of sexual intercourse, particularly between their parents.

primary care physician Physician who specializes in family medicine, internal medicine, pediatrics, and obstetrics and gynecology; many believe psychiatry should be designated a primary care specialty.

primary diagnosis Major emotional disorder for which the patient is treated. Also called principal diagnosis.

primary gain Reduction of anxiety achieved by a defense mechanism; relief from tension or conflict through neurotic illness. *Compare* secondary gain.

primary narcissism *See* narcissism.

primary parkinsonism *See* parkinsonism.

primary prevention *See* preventive psychiatry.

primary process thinking In psychoanalysis, the mental activity directly related to the functions of the id and characteristic of unconscious mental processes; marked by primitive, prelogic thinking and by the tendency to seek immediate discharge and gratification of instinctual demands. Includes thinking that is dereistic, illogic, and magical; normally found in dreams, abnormally in psychosis. *Compare* secondary process thinking.

primary reinforcer *See* reinforcement.

primary retarded ejaculation Lifelong inability to ejaculate during coitus. *Compare* secondary ejaculation.

primitive idealization Defense mechanism in which external objects that are viewed as either “all good” or “all bad” are unrealistically endowed with great power; most commonly, the “all good” object is

Telegram: @medical_k

www.konkur.in

seen as omnipotent, or ideal, while the badness of the “all bad” object is greatly inflated.

Prince, Morton (1854–1929) American neurologist and psychiatrist known for his study of multiple personalities.

principal diagnosis PRIMARY DIAGNOSIS.

prion disease A class of disorders caused by a transmissible infectious protein. Includes Creutzfeldt–Jakob disease (CJD), Gerstmann–Straussler–Scheinker disorder, kuru, and fatal familial insomnia.

prison neurosis *See* chronophobia.

prison psychosis Psychotic reaction to incarceration or to the prospect of incarceration.

privacy 1. Limiting access of others to one’s body or mind, including dreams, fantasies, thoughts, or beliefs. **2.** Freedom from intrusion by the state or third persons. **3.** Restricted areas of personal decision, usually in such matters as personal association, abortion, or bodily integrity.

privilege Legal term referring to the legal right of patients to prevent their physicians from testifying about information obtained in the course of treatment; the legal formulation of the ethical principle of confidentiality. In some states, information obtained in the course of the doctor–patient relationship is considered privileged communication.

privileged communication *See* privilege.

PRO Peer Review Organization.

probability Quantitative statement of the likelihood that an event will occur. A probability of 0 means that the event is certain not to occur; a probability of 1.0 means the event will occur with certainty.

problem-oriented record Method for organizing a patient’s clinical chart, consisting of five parts: data base, problem list, treatment plan, progress notes, and discharge summary.

problem-solving Capacity of a person to master a new or novel task.

Telegram: @medical_k

www.konkur.in

process schizophrenia Unofficial term for schizophrenia attributed more to endogenous factors than to specific environmental influences. *Compare* reactive schizophrenia.

prodrome Early symptom of a disease, often serving as a warning or premonitory sign of the approach of a morbid condition; for example, the aura preceding an epileptic seizure or classic migraine.

Professional Standards Review Organization (PSRO) Organization of physicians in a given region established to review the quality of health care services, particularly with regard to whether the inpatient services rendered are medically necessary. Such an organization has been required by federal law since 1972 in relation to hospital care under Medicare and Medicaid. *See also* peer review organization; utilization review committee.

profound mental retardation *See* mental retardation.

prognosis 1. Opinion as to the probable future course, extent, and outcome of an illness. **2.** Specific goals of therapy.

projection Unconscious defense mechanism in which a person attributes to another those generally unconscious ideas, thoughts, feelings, and impulses that are in themself undesirable or unacceptable as a form of protection from anxiety arising from an inner conflict; by externalizing whatever is unacceptable, the person deals with it as a situation apart from themselves. *See also* blind spot.

projective identification Defense mechanism in which unwanted aspects of the self are projected onto another person such that the individual projecting feels at one with the object of the projection. It allows one to distance and make oneself understood by exerting pressure on another individual to experience feelings similar to one's own.

projective test Psychological test with loosely structured test material that requires the subject to reveal their own feelings, personality, or psychopathology; for example, Rorschach Test, Thematic Apperception Test.

prolactin Anterior pituitary hormone that has been studied as a potential index of dopamine activity and receptor sensitivity in

Telegram: @medical_k

www.konkur.in

studies of central nervous system function in psychiatric patients.
